Presentation and Discussion	8
State Water Project	8
Afternoon Session	122
Closing Remarks	166
Adjournment	166
Certificate of Reporter	167

1 P R O C E E D I N G S

2 MR. TRASK: I apologize for our  
3 technical difficulties. Our projector up here  
4 decided not to work today, so we had to scramble  
5 and put in a back up system.

6 We are now being broadcast over the  
7 internet. I need to get the tele-conference  
8 going.

9 In the 2004 update to the Integrated  
10 Energy Policy Report, the Energy Commission  
11 adopted an official policy such that the Energy  
12 Commission should work with the PUC, utilities,  
13 DWR, and other agencies to explore the potential  
14 to I guess optimize and/or increase pumped storage  
15 capacity, generating capacity in the state.

16 Part of our working group and part of  
17 the water energy relationship has been to look at  
18 generation in water system in general, not main  
19 hydro-electric projects, but rather things like  
20 conduit hydro-electric, digester gas generation  
21 from waste water, things like that.

22 Pumped storage is something that  
23 definitely the Commission is highly interested in.  
24 I think there is probably more interest now that  
25 people are looking towards this 30 percent goal

1 for renewable energy in the state and being  
2 essentially no other way to store electricity with  
3 any sort of efficiency other than pumped storage.

4 I guess what we have here is an  
5 opportunity to get in on the ground floor  
6 here on a planning effort. I guess you would say  
7 just a coordinated effort to explore the potential  
8 for using pumped storage more efficiently for the  
9 existing facilities and to develop new facilities,  
10 especially related to the development of renewable  
11 energy I think is probably the main focus.

12 Today we are going to have a  
13 presentation from the State Water Project folks  
14 and from DWR across the street, and they are going  
15 to talk about pumped storage limitations in their  
16 systems, and then I think we will open it up to a  
17 discussion of where we want to go from  
18 here.

19 I should let you know the study which we  
20 will talk about a little bit later will be coming  
21 out here in a week to two weeks. After which, we  
22 will have another two weeks for people to review  
23 it publicly, and then we will have our IEPR  
24 workshop, the committee workshop on June 21. That  
25 is a Tuesday. Then we will turn to doing

1 recommendations to the committee and to the  
2 Commission for policy. That could Energy  
3 Commission policy, other state agency policy, it  
4 could be legislation recommendations. It is  
5 virtually wide open.

6       The study has some of the staff  
7 recommendations in it, but they are more sort of  
8 on the staff level, the kind of things we are  
9 recommending to our executive director.

10       Coming out of this -- following this  
11 will be another effort to do policy  
12 recommendations and that will go to the committee,  
13 and that will be part of the IEPR, it won't be  
14 part of our study. It could be things like well,  
15 for instance in the treatment world, we know we  
16 have a lot of new water treatment rules coming  
17 out, and not too much information about what they  
18 could mean energy wise.

19       We are thinking that about a rough  
20 doubling of electric demand due to these new water  
21 quality regulations, so there may be a  
22 recommendation coming out of it such as the  
23 Department of Health Services, anybody involved in  
24 water quality regulation.

25       We consider energy use in their

1 regulations, at least try to give some level of  
2 quantification as to the impact on the electric  
3 system, those kinds of things.

4       Possibly, water system generation. What  
5 we could do to maximize what we have, optimize  
6 what we have, what we could do to add  
7 incrementally at existing facilities, new  
8 facilities, pretty much wide open.

9       Personally, I'm not sure exactly what  
10 I'll be doing, but I am going to pull out  
11 of this study rotation once it gets a little crazy  
12 around here and go hopefully just to work on what  
13 we think will be the next phase of this study  
14 which will be a comprehensive program starting  
15 with a clearing house of information to assist  
16 water system professionals in managing energy in  
17 their systems.

18       After that, I think I will probably be  
19 leaving, so since I am a consultant, and hopefully  
20 somebody on staff will be picking up this effort  
21 and carrying it on because I do think this is a  
22 vital planning effort that really needs to be  
23 done, and personally I think that is one of the  
24 bigger problems we have is we have all these  
25 planning, but we rarely have time or resources to

1 carry it through to policy and real world changes.

2 That is the opportunity here.

3 Any opening comments, general comments,

4 where we are, where we are going?

5 MR. WOODWARD: You probably want to

6 introduce folks that are here.

7 MR. TRASK: Sure. Let's just go around

8 the room and introduce ourselves.

9 MR. HOUSE: I'm Lon House. I am an

10 energy advisor to the Association of California Water Agencies.

11 MR. WOODWARD: Jim Woodward with the

12 California Energy Commission in the Electricity

13 Analysis office. Do you want to tell people what

14 you've just handed out?

15 MR. HOUSE: What I've handed out is a

16 summary of the blueprint for California water. It

17 is not the full document, it is just an executive

18 summary of a study and recommendations of the

19 water agencies in this state put together. It was

20 released at the ACWA Conference on May 6, so some

21 of the stuff you haven't had a chance to put in to

22 your document, and I will be filing the full

23 document with docket, but this is just in summary,

24 it looks at what California is facing in the

25 future and it provides a blueprint for getting the

1 future with various things.

2 We can go through it at some point, but  
3 this is actually more for additional input to the  
4 white paper that you have done.

5 MR. TRASK: I can see us going over that  
6 either this afternoon or on Thursday as part of  
7 comments on this study because very definitely it  
8 is new information that we should get in there.

9 MR. KLEIN: Gary Klein with the  
10 California Energy Commission.

11 MS. PARK: Laurie Park with Navigant  
12 Consulting.

13 MS. BURTON: Liz Burton with Lawrence  
14 Livermore National Laboratory.

15 MS. NEWMARK: Robin Newmark also with  
16 Lawrence Livermore National Laboratory.

17 MR. ZASSO: Tio Zasso, DWR.

18 MR. BUI: Tuan Bui, DWR.

19 MR. QUALLEY: George Qualley, DWR power  
20 planning and contracts management, and we are not  
21 from DWR across the street. We are from the DWR  
22 at the General Operations Center.

23 UNIDENTIFIED VOICE: Apparently, that  
24 makes sense to everybody here, right?

25 MR. QUALLEY: We are Project Operations.

1 UNIDENTIFIED VOICE: Got it.

2 MR. TRASK: Monica.

3 MS. RUDMAN: Monica Rudman, California  
4 Energy Commission.

5 MR. BROOME: Ken Broome, KR Broome and  
6 Associates Consulting Engineers.

7 MR. JOHNSON: Craig Johnson, State Water  
8 Contractors.

9 MR. TRASK: I don't know if I introduced  
10 myself. I'm Matt Trask, the Project Manager for  
11 the Water Energy Relationship Study.

12 MR. CROOKS: I'm Tom Crooks with  
13 Navigant Consulting.

14 MR. TRASK: Tom has been putting  
15 together Appendix D, which is something we will go  
16 over later on, what I consider sort of the  
17 gist of this study which is trying to do a cost  
18 base or avoid the cost base analysis of existing  
19 water conservation efficiency programs and  
20 determine the energy cost and/or benefit from  
21 those.

22 That is establishing or setting  
23 the ground work for that clearing house of  
24 information that I mentioned earlier. We already  
25 have quite a bit of information out there. We do

1 have a web page, the Energy Commission does just  
2 for water, so we will probably be expanding that  
3 and using a lot of Tom's work as kind of the basis  
4 for that.

5 All right, I think we will start with  
6 the presentation from Tio and Tuan here. You guys  
7 want to do it from there, or do you want to come  
8 up and play with the machine. How do you want  
9 to --

10 MR. BUI: I can do it from here.

11 MR. ZASSO: Just as a way of  
12 introduction, back in January, Bill Forsythe from  
13 the Department gave a presentation, an  
14 overview of the State Water Project operations,  
15 and I think he might have just touched on pumped  
16 storage, but that has become a topic of discussion  
17 obviously in the white paper and of interest  
18 today. So, I thought it would be a good idea to  
19 hear it directly from the folks over the operation  
20 center that are involved in trying to make pumped  
21 storage work whenever the opportunity arise.

22 MR. WOODWARD: This will be in the State  
23 Water Project facilities?

24 MR. ZASSO: Yes, that's correct.

25 MR. WOODWARD: Okay, good.

1 MR. BUI: That's correct. I was  
2 volunteered to make this short presentation here.  
3 My co-worker of mine got jury duty, so I am ending  
4 up with the pleasure of giving this presentation?

5 MR. TRASK: Could you move that mike  
6 over in case there is anyone listening on the  
7 broadcast? That is the only one that goes out.  
8 That is for the court reporter there, the little  
9 one.

10 MR. BUI: Basically, I have with me Tio  
11 Zasso, what I call him is a walking encyclopedia  
12 of the State Water Project, just to help me out.  
13 This is a short presentation of the State Water  
14 Project overview, and then we will go into the  
15 pump back facilities.

16 I will be covering the Oroville Complex.  
17 I will be covering the San Luis Joint Use Complex,  
18 and then we can stick around for a few minutes for  
19 as long as necessary like George said for  
20 questions and answers.

21 Let's start with the presentation slide  
22 No. 1. Basically I thought I would show the  
23 department's mission, the mission is up there for  
24 you to go over. It basically revolves  
25 around managing the water resources. The State of

1 California and conserve and deliver the water to  
2 California while meeting all the recreation, flood  
3 control, environmental enhancements, and so on to  
4 provide benefits to Californians. Pretty much the  
5 missions for both DWR and O & M revolve around  
6 water.

7       The next slide will show the State Water  
8 Project map. The State Water Project started with  
9 Oroville in the north, the largest reservoir of  
10 the State Water Project with about 3.5 million  
11 acre feet of storage and then on down to North Bay  
12 Aqueduct, which takes water out of the Delta and  
13 provides water to Napa, Solano County, and then on  
14 down to South Bay providing water to Santa Clara.

15       Then you are entering into two divisions  
16 with the San Luis Reservoir, which is one of the  
17 largest off-stream storage in the State Water  
18 Project south of Banks Pumping plants.

19       Basically, it is a Joint-Use facility  
20 between the Department of Water Resources, the  
21 State Water Project, and the Central Valley  
22 Project.

23       Then move on down to the Coastal Branch  
24 which serves the water user from -- the Coastal  
25 Branch serves water user in the Santa Barbara and

1 San Luis Obispo area.

2 Moving on down to the Aqueduct in  
3 Southern California, we have the west branch and  
4 east branch serving Southern California.

5 The next slide shows the profile of the  
6 statewide project starting with Oroville around  
7 900 feet elevation. We have a pump gen power  
8 plant there, so we are going to go into detail in  
9 a little bit in the presentation.

10 We move on down to Banks Pumping Plant  
11 which captures the water entering the -- that is  
12 the start of the California Aqueduct.

13 The Dos Amigos Pumping Plant is the  
14 largest pumping plant in the State Water Project  
15 which is joint-use between the state and the  
16 bureau with a capacity of about 15,000 CFS or so.

17 Water continues to travel on down to  
18 here you see the Coastal Branch basically with the  
19 highest elevation of around 2,000 feet. Go over  
20 the field and entering Santa Barbara and San Luis  
21 Obispo Counties.

22 Water continues to convey through what  
23 we call the Valley Stream starting with Buena  
24 Vista Pumping Plant on down to Edmunston, which is  
25 one of the highest single lift pump in the world,

1 lifting water from approximately about 2,000 feet  
2 to an elevation of a little over 3,000 feet  
3 elevation entering Southern California, split from  
4 the West Branch and East Branch, west, east,  
5 ending to determined reservoirs, one is Castaic  
6 with the East Branch and Lake Perris West Branch.

7 Along the way, basically, we have a lot  
8 of recovery generation plants, Warren, Alamo,  
9 Mojave Siphon and on down to Devil Canyon.

10 MR. WOODWARD: What about on the Coastal  
11 Branch?

12 MR. BUI: The Coastal Branch basically  
13 pretty much lift there, there is no generation  
14 there at all.

15 MR. WOODWARD: There is none on that  
16 side?

17 MR. BUI: No, not on that side.

18 MR. WOODWARD: Is there potential or is  
19 it just was never planned into the system?

20 MR. BUI: It is not planned in the  
21 system, I don't know if the economic justification  
22 is there to build a pumping plant there.

23 MR. ZASSO: It is typically very low  
24 flow, roughly around 100 CFS, 110 CFS, it is a  
25 small pipeline.

1 MR. WOODWARD: Thank you.

2 MR. TRASK: Are there any pressure  
3 relief facilities on it or anything like that?

4 MR. ZASSO: There are some, yes. Some  
5 of it is pipeline, so there are some air release  
6 systems on that, but typically, it is mostly  
7 pipeline.

8 MR. TRASK: If you don't mind us  
9 interrupting your presentation here, what kind of  
10 planning do you do? Is there on-going planning to  
11 look at getting increased generation out like  
12 perhaps here.

13 MR. ZASSO: On the Coastal pipeline?

14 MR. TRASK: Or anywhere, the whole  
15 system.

16 MR. QUALLEY: Periodically, we are kind  
17 of an on-going process to look for opportunities,  
18 I couldn't give any specifics on what the  
19 analytical thinking was on the Coastal, but  
20 obviously it is advantageous to the State Water  
21 Project and to benefit the contractors to put in  
22 recovery generation wherever we could put it.

23 We have like a small three MW unit up at  
24 the Thermalito Diversion Dam, and we have some  
25 other small facilities, so we are on the lookout

1 for it, but it has to pass the test of economics.  
2 Once again, it is an on-going process. Sometimes  
3 it might not pass the test or whatever the  
4 conditions are at the time. A few years down the  
5 road maybe it does, so we need to keep revisiting  
6 these things.

7 MR. BUI: Recently there is an  
8 investigation regarding putting a hydro unit at  
9 the Thermalito at the river outlet, but I don't  
10 know what came about from it.

11 MR. ZASSO: Actually, I've been in  
12 operations since '94, we have actually had two  
13 inquiries about putting in a recovery unit at the  
14 river outlet, and in neither case the economics of  
15 the cost of implementing the facility is enough to  
16 justify actually installing it. It is typically  
17 very low head, a lot of flow, but typically no  
18 head there, it is very small drop going into the  
19 low flow section of the Feather River.

20 One example of our on-going review for  
21 energy facilities, back in the 90's we built and  
22 made commercial at the Mojave Siphon Powerplant,  
23 on this slide right up there in Southern  
24 California in between our Pearblossom Pumping  
25 Plant and going into Lake Silverwood. We have

1 three units there and saw that as an opportunity  
2 to our energy portfolio that way.

3 MR. BUI: Continue maintenance and  
4 practices. We just want to make sure that we have  
5 units running. It would be advantageous to keep  
6 the units running generally and supplement our  
7 energy requirement.

8 MR. QUALLEY: There were some facilities  
9 that came along in the development of the State  
10 Water Project when the project was first built the  
11 Alamo Power Plant there, it was known as the  
12 Cottonwood Shoots where the water was flowing  
13 through a drop there, and they were trying to get  
14 the project built within the money that was  
15 available in the bonds. They weren't building any  
16 extra things at that time, then later on in the  
17 80's when it made sense to do that, then the Alamo  
18 Power was (inaudible).

19 MR. TRASK: It was developed later?

20 MR. QUALLEY: Where it was just dropping  
21 the water into pyramid and then built the power  
22 plant when it made sense.

23 MR. ZASSO: One thing to remember is  
24 that any facility augmentation that we have has to  
25 be done at the same time as we are making

1 deliveries. We provide water to the State of  
2 California year round, 24 hours a day, seven days  
3 a week. Any augmentation, addition, even  
4 maintenance has to be phased in and scheduled to  
5 lessen the impact to our deliveries.

6 MR. TRASK: Going back to the Coastal  
7 Branch, you said it is very low flow, 100 CFS. I  
8 would assume it is also pretty variable through  
9 the year?

10 MR. ZASSO: It would be very low in the  
11 winter time, and then it picks up again, peaks in  
12 the summertime, but again, it is very low flow.

13 MR. WOODWARD: Fair amount of head, but  
14 flow, the opposite of the Thermalito one.

15 MR. BUI: Yes.

16 MR. TRASK: Right.

17 MR. WOODWARD: You've got a couple of  
18 thousand feet to come back down if I am not  
19 mistaken, but not much water moving?

20 MR. TRASK: 100 CFS, is that the maximum  
21 flow?

22 MR. ZASSO: Correct. That is what the  
23 power plant is designed for. There is at the  
24 Polonio Pass, Bluestone, and Devils Den Pumping  
25 Plants, there are six units available there. One

1 is one unit, one pump unit at each of those  
2 facilities is a spare, so we will technically run  
3 with five at a maximum. Again, we are only  
4 looking at maximum flows pretty much in the late  
5 spring through the summer time, and then it drops  
6 off in the fall time.

7 MR. BUI: Continue on to the next slide  
8 please. Basically, I am putting some of the  
9 bullets up there just to demonstrate the fact that  
10 we are moving water from where it is to where it  
11 is not.

12 As you know, we have one of the wettest  
13 Mays on record this year, and the year type this  
14 year is below normal (indiscernible).

15 MR. WOODWARD: What is below normal?

16 MR. BUI: Below normal, the year type.

17 MR. WOODWARD: I don't understand,  
18 the --

19 MR. BUI: Hydrological year type.

20 MR. WOODWARD: Okay.

21 MR. BUI: They classify a certain flow  
22 on the (indiscernible) for the Sierras and it  
23 depends on the index, it can be either wet, dry,  
24 and so on.

25 MR. WOODWARD: For the Sacramento Valley

1 water type. We are having a low hydrological  
2 year, but the wettest May on record?

3 MR. BUI: Yes.

4 MR. WOODWARD: Sort of the opposite last  
5 year, right, the driest May on record?

6 MR. BUI: Last year I believe it is an  
7 above normal year. Chris, do you remember? No?  
8 Yeah, I just don't remember.

9 MR. WOODWARD: We had a really bad month  
10 or two last year, we had some really dry weather  
11 last year if I am remembering right.

12 MR. BUI: Yeah, up to the third week of  
13 March of this year, we thought we were going to  
14 have a dry year, and then the last week of March,  
15 you know, the weather developed.

16 MR. QUALLEY: May typically, as you can  
17 expect, doesn't represent a very high percentage  
18 of hydrologic year on the average, so you get a  
19 double or triple May, and it doesn't even compare  
20 to like a normal January or February.

21 MR. BUI: Many job water sources are in  
22 Northern California while the demand are in the  
23 Bay Area, Central Valley, and Southern California.  
24 That is why there is a need to transport water  
25 from north to south.

1 I thought the next statistic kind of  
2 interesting, 70 percent of the total stream run  
3 off is north of Sacramento if you use Sacramento  
4 as a mark. 80 percent of the water demands  
5 basically (indiscernible) in Sacramento, that is  
6 why the State Water Project is there.

7 Some of the facts of the State Water  
8 Project. State Water Project is the largest state  
9 built multiple water project in the United States.  
10 Designed, built, and now operated and maintained  
11 by the Department of Water Resources.

12 We are the largest power consumer in  
13 California. We have pump lows capacity of 2600  
14 MW. To date, I think the pump lows are about 2200  
15 MW to date the highest. We are also the --

16 MR. WOODWARD: I'm sorry, you have  
17 capacity at 2600, but you don't usually hit it --

18 MR. ZASSO: Correct.

19 MR. BUI: Right.

20 MR. WOODWARD: -- you are a few hundred  
21 below.

22 MR. ZASSO: Yes. Tuan allows me to take  
23 units in and out of service to maintain them.

24 MR. BUI: Basically I am on the power  
25 planning and Tio is running the outage managing,

1 we are -- it is an aeriative process. He would  
2 like to take units off for maintenance, and I  
3 whether or not tell him that, you know, maybe it  
4 is wise to move it on a certain month because it  
5 interferes with water deliveries.

6 We are the fourth largest power  
7 generator in California. We have an instore  
8 capacity of just over 1,500 MWs in our system.

9 Almost all of our generations are  
10 renewable, generations hydro power.

11 MR. WOODWARD: Most of it is water  
12 running back downhill somewhere?

13 MR. BUI: Yes. I would say 99.  
14 something percent except for (indiscernible) which  
15 is the unit, the coal unit that we own in Nevada.  
16 That is the only unit (indiscernible) coal power  
17 plant, the rest of them are hydro power.

18 MR. WOODWARD: No natural gas state in-  
19 state or anything else?

20 MR. BUI: No natural gas, not that I am  
21 aware of.

22 Continuing with the overview, basically,  
23 the state water contractors, there are over 29  
24 public water agencies that sign long-term  
25 contracts with the Department of Water Resources.

1 They serve over 20 million Californians with the  
2 latest census. I read somewhere that we are about  
3 34 million in California, so they are serving  
4 about almost two-thirds of California.

5       Irrigates about 900,000 acres of crops,  
6 most of them are in the Central Valley. The  
7 financing of the State Water Project in the 1960  
8 voters passed the \$1.7 billion bond and started  
9 the initial construction of the State Water  
10 Project. Since then, the cost has been -- the  
11 water contractors are pre-paying those bonds with  
12 interest. They are also paying all the design,  
13 maintenance and constructions, any costs  
14 associated with the State Water Project are paid  
15 by the water contractor.

16       Going on to the State Water Project  
17 facilities, we have 21 major storage facilities  
18 starting with as I mentioned earlier Oroville in  
19 the north with 3.5 million acre feet for storage.

20       With Castaic Lake on the West Branch,  
21 and Perris on the East Branch in Southern  
22 California. We have 29 pumping plants and  
23 generating in the State Water Project. Again, the  
24 largest generation plant is Hyatt in Oroville.  
25 The largest pumping plants once again

1 (indiscernible). We have over 670 miles of canals  
2 and pipeline to transport water from the north to  
3 the south.

4 Our water delivery of the State Water  
5 Project, maximum entitlement is 4.1 million acre  
6 feet contractual between the Department of Water  
7 Resources and the state water contractor.

8 The average annual delivery to date is  
9 about 3 million acre feet, and the split between  
10 the end user MNI about 50/50.

11 MR. WOODWARD: MNI is --

12 MR. QUALLEY: Just a comment on that  
13 first item, we are probably not supposed to use  
14 the word "entitlement" anymore. It should  
15 probably say Table A, that's the maximum that was  
16 originally contracted for, and that is the basis  
17 for establishing the cost that are charged to the  
18 contract, but the project as it currently sits  
19 can't deliver 4.13, but that is what the original  
20 design in the original contracts were signed for.

21 MR. TRASK: What is the maximum you  
22 could deliver?

23 MR. QUALLEY: We are probably looking at  
24 it this year --

25 MR. BUI: Systems peak --

1           MR. QUALLEY: So far in history, it has  
2   been 3.6 million acre feet.

3           MR. WOODWARD: Is that what the system  
4   is capable of delivering? I'm sorry, I am  
5   ignorant here. I am relatively new to California,  
6   and some of this stuff is like Greek. A little  
7   bit of history would be helpful. The intent was  
8   to figure out to deliver just over 4 million acre  
9   feet a year or something like that. That was the  
10   original intent when back in the 60's when the  
11   project was started, right?

12          MR. BUI: Yes.

13          MR. QUALLEY: To deliver that amount, you  
14   would have to have a delta transfer facility which  
15   some people would refer to it peripheral canal,  
16   and that was part of the original design of the  
17   project. (Indiscernible) to more efficiently get  
18   the water through the delta would be required to  
19   get the 4.13. Obviously that is not in place.  
20   So, with the facility as currently configured, our  
21   experience to date has been about 3.6 million. It  
22   depends on a lot of different factors. I mean,  
23   you have to have a lot of combination of things  
24   coming together. It is not just a total amount of  
25   rainfall you get in a year. It depends on when

1 you get it, if (indiscernible) is healthy, you can  
2 get a lot of precip and have it raw off early in  
3 the year and wind up not filling your reservoirs.

4 Or you can get really cold storms in a  
5 below normal year like this year, and you are in  
6 great shape because of it. The snow pack is up  
7 (indiscernible). So, a lot of things play into,  
8 you know, the total amount you can wind up  
9 delivering in the system.

10 MR. BUI: Earlier, I mentioned MNI. MNI  
11 is Municipal Industrial.

12 MR. ZASSO: Going back to the demand  
13 pattern. Looking at the split of about 50/50 for  
14 agriculture and urban, your agriculture demand  
15 will start picking up in the later winter/early  
16 spring, peak in the summer time, and then start  
17 dropping off in the fall, and I have I call it a  
18 maintenance level through the winter time. Your  
19 urban, your MNI, that is a little more flat type  
20 of demand pattern. It will typically drop some in  
21 the winter time, again, peak in the summer. It is  
22 typically a flatter pattern throughout the year.

23 MR. WOODWARD: Certainly compared to the  
24 ag.

25 MR. BUI: Yes.

1 MR. ZASSO: Compared to the ag, yes.

2 Will we ever get over 3.6 million acre feet  
3 delivered? Potentially.

4 MR. WOODWARD: You need some additional  
5 infrastructure in order to move, to have the  
6 capability of moving the water out of the Delta  
7 into the canals if I am hearing correctly.

8 MR. ZASSO: The year we moved 33.6  
9 million acre feet, we are doing that with our  
10 current facilities that we have. Basically we  
11 have to have the demand in order to move the water  
12 supply, either ag or urban. We've got to have a  
13 place to put it.

14 MR. TRASK: Tio, I assume right now that  
15 you have already filled or are filling San Luis as  
16 much as you can?

17 MR. ZASSO: Actually, we filled it.

18 MR. TRASK: It is full, okay.

19 MR. ZASSO: As I'll get into later, we  
20 are actually starting on our yearly cycle downward  
21 for delivery.

22 MR. TRASK: So, if you are going to get  
23 that, I'll hold off.

24 MR. ZASSO: Yeah, I'll cover that.

25 MR. BUI: It will be in Tio's

1 presentation. State Water Projects operation  
2 basically in Sacramento we have an operation  
3 control office. We direct planning, the overall  
4 water and power operation of the State Water  
5 Project.

6       The fuel divisions are basically located  
7 throughout the state. In the north we have  
8 Oroville, in the south we have few divisions.  
9 Basically, they carry out directives of those OCO,  
10 Operation Control Office. We tried to preserve  
11 waters, provide water supply within the  
12 constraints of flood control and environmental  
13 requirements and others which I will get into a  
14 little bit.

15       With the water constraints we have  
16 maximize our off-peak pumping when it is cheapest,  
17 and we optimize our on-peak generations when it is  
18 the most value.

19       I would like to emphasize basically the  
20 power production of the State Water Project is  
21 basically the by-product of the water operations.  
22 The goal is to deliver the water first and power  
23 generation came with it, not the other way around.

24       MR. QUALLEY: That's not to say that we  
25 are not making upwards to be as efficient as we

1 can in our power operations. Obviously we want to  
2 do that. We have to minimize the net cost of the  
3 contractors, but we have to deliver the water.

4 MR. BUI: Exactly.

5 MR. WOODWARD: How are you doing on net?

6 I mean, if I understand what you just described  
7 about pumping as much off-peak and producing as  
8 much as you can on-peak, what is your annual net  
9 look like?

10 MR. BUI: We are over all the net  
11 consumer. What we are trying to do is we tried to  
12 play as much on peak generation as possible to  
13 offset some of the -- did I say off-peak -- on-  
14 peak generation as much as possible. Offset for  
15 some of the costs that we have to purchase power  
16 during the off-peak hours.

17 MR. WOODWARD: I assume someone actually  
18 pays you more during on-peak for electricity than  
19 you pay off-peak to buy it, at least I am hoping  
20 that's true.

21 MR. BUI: We also entering long term  
22 agreement with the utilities to doing exchange  
23 type. Basically, we provide on-peak generations  
24 for them to supply for their urban lows and then  
25 in the off-peak, they provide us with power so we

1 can pump the water from north to south.

2 MR. TRASK: Since the utilities don't  
3 really own much in the way of generation, how is  
4 that working, or is it just coming from the  
5 nuclear plant?

6 MR. QUALLEY: We are probably never going  
7 to have a situation like we have with Edison where  
8 we had one huge contract that basically dealt with  
9 about two-thirds of the power needs. That was a 20  
10 year contract that expired at the end of December.

11 What we are looking at now is there will  
12 be a cost of evolution of a power portfolio where  
13 we want to maintain a good mix from all  
14 standpoints really, from fuel source, from the  
15 counter parties to mitigate the credit risk, you  
16 know, the sources, the locations, just --

17 MR. TRASK: You are just out there every  
18 day in the markets seeing what you can find --

19 MR. QUALLEY: It is a mix of short term  
20 transactions, mid term, and long term  
21 transactions. We are in the process of building  
22 the portfolio. We will always be in the process  
23 of actively managing it and turning it over, and  
24 we want to have a variety of terms. We've got  
25 contracts beginning and ending at different times,

1 so that we don't get stuck to any one fundamental  
2 assumption of how the market is going to go. We  
3 want to be in a position where we can change as  
4 the market changes and take advantage of other  
5 opportunities and new technologies.

6 MR. TRASK: Is it the same people that  
7 handle both your purchasing and selling?

8 MR. QUALLEY: The staffs work closely  
9 together, Operations and Control Office, they are  
10 dealing with the shorter term transactions.

11 MR. TRASK: I'm just curious because it  
12 is part of the reorganization that was announced  
13 is that the purchasing people would be coming to  
14 the new Department of Energy with the  
15 generating --

16 MR. QUALLEY: (Indiscernible).

17 MR. ZASSO: (Indiscernible).

18 MR. QUALLEY: We are all just project --

19 MR. ZASSO: State Water Projects.

20 MR. BUI: This is strictly State Water  
21 Project that we are talking about.

22 MS. NEWMARK: I was at a water  
23 conference last week at which where someone from I  
24 think Southern California Edison pointed out that  
25 during the brown-out period last year, the State

1 Water Project actually shut in some of your  
2 pumping during peak times and just slowed down the  
3 water. I would like to know if this is true, and  
4 the extent to which it is true that your actual  
5 pumping facilities, your working against the power  
6 crisis in the state. Is that a true fact? To the  
7 extent to which it is true would be helpful to  
8 know.

9 MR. QUALLEY: There were times during the  
10 crisis that State Water Project did respond to  
11 help out the situation. One thing we've got to  
12 keep in mind is that as Tuan said, most of the  
13 State Water Project pumping is in the off-peak  
14 period, so we are typically not out there adding  
15 to the problem in the on-peak period. We do some  
16 on-peak pumping in the shorter hours, but we very  
17 rarely do any pumping in the --

18 MR. BUI: (Indiscernible).

19 MR. QUALLEY: -- (indiscernible) peak  
20 period. So, just with our normal operations, we  
21 are usually helping the situation rather than  
22 hurting the situation. There were some times even  
23 during those shorter periods where we were in the  
24 position of where upon the request of the  
25 independent system operator during a Stage 3

1 emergency, we are going to (indiscernible) some  
2 load and help out with the overall situation.

3 MR. ZASSO: One thing you have to  
4 remember, every time we are asked to shed load for  
5 an event like that or an event where we program,  
6 it is within the confines and the operational  
7 parameters of our system. If we shut off pumps  
8 pumping over the hill to help out the grid, we are  
9 still going to make deliveries. We have scheduled  
10 deliveries independent store contractors down  
11 stream. They are not going to shut off their  
12 demand mode if you shut off pump pumping.

13 Basically it comes out of storage. We have got to  
14 replace that storage some where along the line.

15 Because one, that is water supply, that  
16 is critical, that is critical as the grid. We  
17 have on our East Branch if you noticed on the  
18 slide earlier, we have not as much installed  
19 storage capacity on the East Branch as we do on  
20 the West Branch. We have about a 70,000 acre foot  
21 reservoir in between the Edmunston and the  
22 terminus reservoir at Lake Perris.

23 If we have a problem or curtailment for  
24 energy reasons, that's where I get water to  
25 deliver. You can only go to that place so many

1 times. Again, it is a constant balance. We can  
2 help the grid out at certain times, but we are  
3 going to make that water up. We are going to have  
4 refill those reservoirs up at other times as we  
5 need to.

6 MR. WOODWARD: Basically that means you  
7 have to run more hours off peak, put another pump  
8 on for awhile to do your makeup or something,  
9 right?

10 MR. ZASSO: What it would typically mean  
11 is that we are going to fill up our light load  
12 pumping hours, our off-peak pump period. We are  
13 going to have to actually probably add more  
14 pumping during the shoulders and potentially into  
15 the on-peak in order to make that water up  
16 downstream.

17 MR. WOODWARD: You are already running  
18 maximum flow during off-peak hours?

19 MR. ZASSO: That's what our target is.

20 MR. WOODWARD: That is what your target  
21 is.

22 MR. ZASSO: That is what our target is,  
23 yes.

24 MR. WOODWARD: You described earlier,  
25 you got a few hundred MW's of pumping in reservoir

1 mostly for maintenance purposes. So, to the  
2 extent you can fill up a bit more in off-peak, you  
3 do, but you have to maintain the stuff, otherwise,  
4 you are in trouble.

5 MR. ZASSO: We are pretty much running  
6 off-peak at capacity. Any other opportunity to  
7 make up any water that we've taken out of storage  
8 is going to come in either the shoulders or the  
9 heavy load period. A good example at Edmunston,  
10 we have 14 units installed there. They are 16 MWs  
11 a piece, they are roughly 325 CFS a piece.

12 We can only run 13 at a time. We are  
13 hydrologically limited due to the configuration.  
14 That allows me to have one unit out of service  
15 throughout the year and still not have any impact  
16 on our capacity to deliver water. So, I am going  
17 to fill up in the light load, I'm going to run 13  
18 units at night.

19 MR. WOODWARD: All the time?

20 MR. ZASSO: Most of the time.

21 MR. WOODWARD: Just move water up and  
22 get it into storage.

23 MR. BUI: When the demands are there.

24 MR. ZASSO: Right, when the demand is  
25 there. If I curtail for any reason, and I take

1 storage downstream, if we are filling up the  
2 shoulders hours are filled up, I've got to add  
3 some extra pumping in heavy load to get there.

4 MR. BUI: Basically, there is another  
5 aqueduct. In our reservoirs, there is a draw down  
6 limitation. So, you can't just drop the elevation  
7 in the canal and in the reservoir too fast,  
8 otherwise you are going to pop all the panels off  
9 the aqueduct. That is one of the operation  
10 constraints as well.

11 MR. WOODWARD: Pop the panels meaning  
12 the side walls come off?

13 MR. BUI: Yes, they come off.

14 MR. TRASK: Right, the soil on the  
15 outside is saturated and if you remove the  
16 pressure from the outside, that soil just pushes  
17 right in.

18 MR. WOODWARD: Clearly as you said  
19 earlier, your mission is delivering water, and  
20 energy is a nice feature and an expense, but your  
21 mission is to deliver water and that is primary,  
22 by at least an order of magnitude or two?

23 MR. ZASSO: Correct.

24 MR. BUI: Yeah, we --

25 MR. WOODWARD: We are not putting

1 (indiscernible), we are going to make sure it is  
2 clear?

3 MR. BUI: Right, yes.

4 MR. ZASSO: Again, on the question that  
5 was brought up, we are in regular communication  
6 interaction with the independent system operator,  
7 with our scheduling coordinator, and schedule our  
8 loads through the ISO, but we are in regular  
9 communication on that very subject.

10 What the State Water Project's operating  
11 constraints are, what we have to offer as far as  
12 things that we can bid into enough to help in the  
13 overall grid operations. I was just at a meeting  
14 a couple of weeks ago where managers from the ISO  
15 and the department got together just to talk about  
16 the subject, so we have a clear understanding of  
17 what each other's needs are and what the  
18 constraints are, so god forbid, get it from other  
19 states for your emergency where things will be  
20 smoother than during a crisis. Hopefully, we  
21 don't have another crisis like that.

22 MR. TRASK: That's why we are here.

23 MR. BUI: That was the end of my State  
24 Water Project overview. If you have any  
25 questions, we are happy to answer it.

1       The next part would be the pumped storage  
2 facilities. I will start with the Oroville  
3 Complex. Tim will finish the presentation with  
4 the San Luis Joint (indiscernible) Complex, and  
5 then we will be around for question and answer.

6       Basically, the principle feature of the  
7 State Water Project is the Oroville Complex, and  
8 the principle feature of the Oroville Complex is,  
9 of course, Lake Oroville, and then you have  
10 Oroville Dam and Lake Oroville, and we have the  
11 Hyatt Power Plant which is about 800 plus MW of  
12 capacity, and then we have the Thermalito  
13 Diversion Dam.

14       From there the water diverts. There is  
15 two ways the water can travel. One is through the  
16 power canal on down to the Thermalito Forebay.  
17 The other is as the water continues on to the  
18 natural channel of the Feather River on down to  
19 the meeting the (indiscernible) of the Sacramento  
20 River.

21       At the Diversion Dam, we have the Fish  
22 Hatchery there. We also have the Thermalito  
23 Diversion Dam Power Plant, which George mentioned  
24 earlier. We have about 3 MW power plant there,  
25 which is primarily used for station service for

1 Oroville.

2       At the end of the Thermalito Forebay, we  
3 have the Thermalito Pumping and Generating Plant  
4 which discharges the water into the after bay.  
5 The after bay is basically primarily used to  
6 maintain uniform flow discharge back into the  
7 Feather River. It is also used as a power  
8 regulation, regulate reservoirs both forebay and  
9 the afterbay, as well as using as a warming basin  
10 for some of the diverters. They would like to  
11 have warmer water than cold water.

12       MR. ZASSO: The primary water uses out  
13 of thermal (indiscernible) off of rice production?

14       MR. BUI: Rice production and the water  
15 rights diverts about in the neighborhood of a  
16 million acre feet a year.

17       MR. TRASK: That is the first I've heard  
18 of that.

19       MR. BUI: The Feather River service  
20 area.

21       MR. TRASK: How much warmer do they like  
22 that rather than --

23       MR. BUI: The next few slides I will  
24 show you how much. Sometimes it is in conflict  
25 with the fish interests.

1 MS. NEWMARK: Where does that water --

2 MR. TRASK: That is what I was going to  
3 get to, yeah.

4 MS. NEWMARK: You actually use the  
5 afterbay as a water source. Where does it come  
6 off the afterbay? You discharge to the Feather  
7 River for water supply and maintenance of the  
8 river itself, is that also the location where the  
9 water goes for water supply, or do you have  
10 another --

11 MR. BUI: There is about four major --

12 MR. ZASSO: (Indiscernible).

13 MR. BUI: Outlets along the --

14 MS. NEWMARK: I don't see it.

15 MR. BUI: It is not on here.

16 MR. ZASSO: There is one here, I think a  
17 couple along here, and some up here.

18 MR. BUI: Two in the north and basically  
19 two in the south of the four basically, these are  
20 the people taking water --

21 MR. ZASSO: Ridgevale.

22 MR. BUI: Ridgevale, Sutter Buttes,  
23 Joint District up there.

24 MR. TRASK: I assume it is a relatively  
25 shallow --

1           MR. BUI: It is a shallow -- it is  
2 basically the afterbay around 136 elevations with  
3 55,000 acre feet of storage.

4           MR. QUALLEY: Just for reference, this is  
5 the river outlet where Tio had mentioned earlier  
6 there had been various efforts to figure out if  
7 there is a power recovery facility that would be  
8 feasible there.

9           MR. BUI: We will go on to the next  
10 slide. Basically, Oroville Dam is the highest,  
11 770 feet highest in the United States along with  
12 two other saddle dams, it empowers Lake Oroville.  
13 Lake Oroville is at the maximum operating storage  
14 of 900 feet. We have about 3.5 million acre feet.

15          MR. QUALLEY: We've got a picture in our  
16 conference room. On June 10 of 2003, it was  
17 899.48. That is hard to do.

18          MR. BUI: You have to just write it just  
19 right without spilling or anything.

20          MR. WOODWARD: You got right up there,  
21 that (indiscernible) was good, huh?

22          MR. QUALLEY: Where the winds were  
23 favorable that day.

24          MR. WOODWARD: Pushing back up the dam,  
25 right, right. Okay.

1           MR. TRASK: I've never seen it in  
2   action, but the spill facility there, what level  
3   does that go. I mean I've seen pictures of it,  
4   and it looks unbelievable.

5           MR. BUI: 901 is the emergency spillway,  
6   and the gated spillway is about 830, 830 feet  
7   elevation, 830 at the bottom of the gated  
8   structure.

9           MR. TRASK: We didn't spill this year I  
10  assume?

11          MR. QUALLEY: Not yet.

12          MR. WOODWARD: What is the lower one  
13  called, I didn't.

14          MR. BUI: The gated structure and the  
15  other one is basically is over the top emergency  
16  spill.

17          MR. WOODWARD: Just over the top, right.

18          MR. QUALLEY: I powered over that in a  
19  helicopter, and it was just towards 150,000. It  
20  was pretty impressive.

21          MR. TRASK: If anybody hasn't seen it  
22  here, it is really impressive. It is just this  
23  big runway of water and then it hits a diversion  
24  and just goes straight up a couple of hundred feet  
25  anyway.

1 MR. BUI: At the end we have an energy  
2 dissipators to prevent a lot of scouring of the  
3 Feather River there.

4 Next slide please. The pumped storage  
5 facilities. Basically locating in the bedrock  
6 underneath Oroville Dam is the Hyatt Power Plant.  
7 The largest of the three plants in the Oroville  
8 Complex.

9 It has six units, three conventional  
10 generations and three pump gen units. The  
11 capacity is about 820 MW with flow capacity of  
12 about 17,000 CFS there.

13 Generator capacity basically varies with  
14 reservoir level, the highest during I think around  
15 June, late May, June, that is when the fill the  
16 reservoir and we drink the reservoir and we go to  
17 September, October, November, and so on.

18 Pumping capacity. We have three units  
19 that have capability of pump gen, about 5,600 CFS  
20 of flow going backward.

21 MR. WOODWARD: The system is pretty much  
22 designed to carry the loads of the way we get  
23 water in California. When water supplies vary  
24 rather dramatically, like lots of precip but no  
25 snow, what happens?

1 MR. BUI: Basically, Oroville is a  
2 multi-purpose dam, we have flood control on there.  
3 The maximum flood control reservation is about  
4 750,000 acre feet. It starts September/October  
5 time there, and it is measured by the wetness  
6 index.

7 We have eight stations that in the  
8 Feather River Basin. It depends on the wetness  
9 index. It dictates how much space we have to  
10 vacate to meet reservoir requirement. So, during  
11 late fall/winter time, we in flood control  
12 operations, the reservoir is (indiscernible) to  
13 its allowable, and that would provide us room to  
14 capture the water, store water, and release as  
15 necessary.

16 MR. TRASK: Does that change through the  
17 season?

18 MR. BUI: It does change through the  
19 season. Starting in September and then ending  
20 around like this time May/June, it depends on how  
21 wet it is. Typical year, we don't have any  
22 reservation flood requirement about this time of  
23 the year.

24 MR. TRASK: One of the things we are  
25 exploring is well, obviously drought is the worse

1 situation, but we are also seeing that if we  
2 shifted to a lot more rain and less snow, that  
3 would have a huge impact on water supplies.

4 For instance, if we started getting to a  
5 situation where we are getting almost all of our  
6 run off say in March, you know, earlier in the  
7 year, would that be even worse for Oroville, would  
8 you always have to keep a little bit of flood  
9 control even into May?

10 MR. BUI: We try to capture as much  
11 water as we can, that is basically, to secure our  
12 winter supply. In March, if I'm not mistaken that  
13 is basically when you have a lot of rain, that  
14 would be the maximum flood control requirement, so  
15 you have to have \$750,000 acre feet empty in the  
16 reservoir to make sure that you would be able to  
17 capture that water if the water showed up.

18 MR. ZASSO: As Tuan mentioned, one of  
19 the parameters that we calculate on a daily basis  
20 is this wetness index. It was established and  
21 developed in accordance with the Corps of  
22 Engineering criteria for the reservoir.

23 It looks at the previous days' wetness  
24 index, today's precip, and takes a percentage of  
25 yesterday's wetness, and calculates a new number

1 for today. That tells us where we are on the  
2 flood control curve.

3 If we are dry and we are down a low  
4 wetness index coming into March, we are allowed a  
5 little bit more. April 1, the curve starts going  
6 up and allows us to start utilizing a little more  
7 space each day as we get out of the rainy season.

8 Typically in March, we are running  
9 pretty much close to that bottom of the flood  
10 control curve that we are allowed to have.

11 MR. TRASK: The curves, are they  
12 constant every year, do they never change?

13 MR. ZASSO: They are the same. Actually  
14 those curves were developed back in 1970 with the  
15 US Army Corp of Engineers.

16 MR. QUALLEY: On your point on the global  
17 warming with the flood reservation that Tuan  
18 talked about that said around 50,000, that  
19 capacity was actually purchased by the Corps of  
20 Engineers when the project was built. So, it is  
21 operated to their criteria for the flood  
22 reservations. Now, if through global warming or  
23 some other reason the hydrologic picture changes  
24 to where you have these warmer storms that it  
25 would change the run off characteristics and so

1 on, right now -- well, initially and I think they  
2 recapped it again a few years ago, they calculate  
3 a level of protection that is provided by that  
4 flood reservation.

5       They would probably go through another  
6 calculation and determine, hey, that is \$750,000  
7 doesn't provide as high as level of protection as  
8 it did years earlier.

9       MR. TRASK: How often do you do that, is  
10 it constant that you reevaluate that?

11       MR. QUALLEY: If the Corps call and want  
12 to do that, basically, they will do it when there  
13 has been enough additional data. They recap it  
14 again after the '97 flood. Either a number of  
15 years have gone by or more importantly some  
16 significant flood events, that tends to change the  
17 statistics over the number of years they look at.

18       MR. WOODWARD: That 750 you pretty much  
19 have to let the level go down that much for flood  
20 control and effectively that has to go down pretty  
21 early, you have to let that drop somewhere in  
22 January you have to start dropping it down or  
23 something like that.

24       MR. BUI: Actually, the flood controls  
25 enter in the curve actually start in September 15,

1 that is the official date that you actually have  
2 to drop. If there is no rain there, basically,  
3 there is no flood control. The index will be  
4 zero, so you can maintain your reservoir as the  
5 level that is desired. As soon as it rains, the  
6 wetness index start to dictate how you operate  
7 during the rainy season.

8 MR. WOODWARD: If your reservoirs are  
9 fuller than the 750,000 on September 15, but there  
10 is no rain, you can keep them there. As soon as  
11 it starts to rain, you have to start going down  
12 that curve to hit the minimum at some point in  
13 order to allow the rains to come later on.

14 MR. QUALLEY: Typically, by the time you  
15 get into November, you are going to have that full  
16 \$750,000.

17 MR. TRASK: You can always drain faster  
18 than it fills?

19 MR. ZASSO: Yeah, at that time of year  
20 in the late fall, there's typically little in-  
21 flow. We are still making deliveries out of  
22 Oroville for our environmental and regulatory  
23 compliance requirements. There is still some  
24 water running for our (indiscernible). The bottom  
25 line, there is not usually a problem with us

1 entering into that season by having it too hot.

2 MR. QUALLEY: Typically our target is

3 what, around a million and a half in the fall?

4 MR. ZASSO: Right.

5 MR. QUALLEY: We have 2 million acre feet

6 there is when you start filling. You typically

7 wouldn't start getting the flood control criteria

8 until late December, more likely in January.

9 MR. ZASSO: If we do encroach into that

10 750,000 acre feet of space, we have to coordinate

11 operations with the Corps of Engineers and our

12 flood center in DWR flood center to plan out and

13 show them this is how we are going to get out of

14 that encroachment.

15 MR. WOODWARD: Have you either

16 separately or together with the Corps of Engineers

17 thought through some of the scenarios that Matt

18 was describing that if you get rain patterns and

19 precipitation patterns radically different from

20 what was originally intended, have you thought

21 through that at all?

22 MR. QUALLEY: I'm out of that loop right

23 now. I used to be in flood management, but that

24 is the type of discussions that would be on going.

25 The Corps is thinking about those type of things

1 all of the time.

2 MR. ZASSO: As far as our office, no, we  
3 haven't entered in to any of those discussions,  
4 different group.

5 MS. NEWMARK: EB Mud has a similar  
6 situation. They own a water shed and have to  
7 monitor and maintain it for flood control, and  
8 they are very concerned about the timing of the  
9 run off and the impact on their flood control  
10 requirements. In fact, they've had to have  
11 negotiations with the Corps of Engineers twice in  
12 the last decade to get some relief on the timing  
13 because in California, we have this drift to  
14 earlier spring run off, but we also have a very  
15 commonly a bimodal precipitation pattern.

16 If you are managing for water supply and  
17 you get a bunch of rain in December and then you  
18 don't have rain in January, the question is when  
19 are you going to get hit in February/March or not.  
20 That is really the question.

21 The Corps of Engineers is evidently very  
22 interested in looking at this general change in  
23 seasonality for just the same reasons that you are  
24 bringing up here, but they haven't been told, they  
25 haven't gotten to the point that they are going to

1 do it yet. I know that the water managers are  
2 also wondering, you know, is there a point where  
3 we need to change the rules based on the  
4 seasonality. Still manage for these requirements,  
5 but maybe move the month, the bench point month  
6 from March to February or September because in  
7 recognition of the trends. I think it is  
8 discussion that should be coming up soon.

9 MR. WOODWARD: Make sure it is a  
10 recommendation, I think, for you all to us. We  
11 ought to get a group of people together to talk it  
12 through a little bit. We have some folks at  
13 Scrips working on sort of climate change weather  
14 issues, and they are doing some earlier  
15 forecasting than normal, and you all might want to  
16 hear about what we are looking at, and they might  
17 want to hear what your issues are. I think we can  
18 set something up to do that just to learn. I  
19 don't know what we should do about it yet, but I  
20 think we ought to take advantage of the folks that  
21 who are thinking about it to bring them all  
22 together and talk about it a little bit.

23 MS. PARK: I also might mention that  
24 among the water people, you -- I'm sorry. I used  
25 to manage the releases for Hetch-Hetchy. There

1 are groups of people that get together regularly  
2 to share forecasting methodologies. All of this  
3 discussion raises some really interesting concerns  
4 on my part that were challenges every day that I  
5 was at Hetchy.

6 First of all, on the forecasting side, I  
7 note that we worked with DWR as well on this  
8 closely. We worked with 76 years of historical  
9 precept. In that 76 year history, you get all  
10 kinds of patterns. So, you know, we weren't as  
11 concerned about the climate change impacts because  
12 we had situations where you had a really heavy  
13 snow pack early in the year such as  
14 November/December. Then you had a pineapple  
15 express come through the first week of December  
16 and everything went down.

17 You have all of those circumstances, you  
18 have circumstances where you have very very wet  
19 years, really nice snow pack, and then nothing  
20 after February. So, you would get in that 76  
21 range of history in theory, you get a pretty good  
22 distribution of all the kinds of occurrences that  
23 you can have.

24 Here is one that I think is really  
25 interesting, and that is a water agency needs to

1 manage its operations for water supply, of course,  
2 and there are some very difficult decisions being  
3 made by people every single day about how to best  
4 protect that water supply.

5       It has to do with precisely that which  
6 is you know what you have as far as precip and  
7 snow up until today, you don't have any idea what  
8 is going to happen tomorrow or the day after. So,  
9 you are constantly trying to manage that both for  
10 flood control purposes and for water supply, and  
11 the power is like the least of your concerns.  
12 Realistically for Hetchy where Hetchy was a very  
13 valuable contributor to the general fund, and that  
14 contribution came from power revenue. There was  
15 more pressure on us all the time to be continually  
16 optimizing that resource.

17       So, here you are, you are faced in  
18 September or October. You've got high power  
19 prices in the market. I could either buy or  
20 generate, and on the water supply side, there is  
21 strong pressure to hold that water. On the power  
22 side, there is great tension to release that  
23 water. The real issue to me always came down to  
24 science, which is we have such a little grasp on  
25 our climate and on our precip, what to expect.

1           There are different services out there  
2   that we paid a lot of money to that told us that  
3   there was a 30 percent probability the year would  
4   look like this. Who is going to bank your whole  
5   water supply on the basis of a 30 percent  
6   forecast.

7           MR. WOODWARD: I like to gamble, you  
8   know.

9           MS. PARK: It is really a very  
10   troublesome thing. At least when I was with  
11   Hetchy, there were a number of studies going on  
12   that we participated in, and I frankly don't know  
13   what the status is of them right now, but some of  
14   them were, for example, to do satellite imaging  
15   out the snow pack to try to estimate the density,  
16   to relate it to prior years as to how dry they  
17   were, you know, and therefore how much run off  
18   would occur and how much would sink into the  
19   ground, etc. It strikes me that maybe the time is  
20   now, maybe because my understanding is the very  
21   same years that Hetchy held on to its water and  
22   then had to release it in a hurry and throw the  
23   water down the mountain without passing it through  
24   the turbines, we were certainly not alone, and  
25   pretty much every hydro generator in California

1 was doing the same thing.

2 I have often wondered how much of an  
3 impact that would have on power if we had better  
4 methods, both for being able to project water  
5 supply, but also maybe what we also need are some  
6 other mechanisms to provide the water supply  
7 hedge, you know. That is where it gets into  
8 things like how valuable is desal.

9 MR. KLEIN: We are making those trade  
10 offs. What would be the key month that you would  
11 like to have more data.

12 MS. PARK: Every single one of them, but  
13 basically, pretty much it was --

14 MR. ZASSO: That will vary from year to  
15 year.

16 MR. WOODWARD: Just to make it simple.

17 MR. ZASSO: Just to make it simple.

18 MS. PARK: Realistically, and you've  
19 been there, right, I mean we had situations where  
20 all of the sudden, we were pouring water down the  
21 mountain in haste, well January '97, but that was  
22 unusual.

23 As we go back in history, and it strikes  
24 me the State Water Project doesn't have as long a  
25 history as some of the operators, you know, we

1 have years on record where we had tremendous snow  
2 packs that came down in November and December and  
3 then very dry periods thereafter, and so what that  
4 really speaks to is the system design flexibility,  
5 the ability to manage these kinds of extreme  
6 conditions, and yet be able to protect, you know,  
7 optimize both our water and power resource  
8 capacity. It is really tricky.

9 MR. TRASK: You are saying the only  
10 thing that is consistent is inconsistency?

11 MS. PARK: There is that, but it also  
12 really speaks to, you know, given that our science  
13 isn't where we need it yet, flexibility in the  
14 system. You know, as I was listening to the  
15 discussion in the State Water Project, for  
16 example, what I heard was that you have a certain  
17 capacity you have to deliver 24/7. If you have  
18 anything that disrupts that pattern, you have to  
19 group it, and then you have to make it up.

20 What would alleviate that and give you  
21 more flexibility, you know, more diameter in the  
22 pipeline, more interim storage capabilities along  
23 the way, something. I mean, there are mechanisms  
24 for building more flexibility into our system such  
25 that we can better optimize the combined water and

1 power resource.

2 MR. KLEIN: Facilities, infrastructure  
3 just like, for example, without advocating through  
4 Delta conveyance or Mojave Desert storage over the  
5 hill might allow for more flexibility in the  
6 dispatch of water.

7 MS. PARK: You know more about your  
8 system that I do. I presume that's true.

9 MR. WOODWARD: Okay. I am assuming the  
10 DWR folks are actually really thinking hard about  
11 this. It is not something you ignore, right?

12 MR. QUALLEY: Yeah, absolutely. I mean  
13 one comment I was going to make, even though the  
14 three of us aren't directly involved in some of  
15 these studies on extreme flood events and global  
16 warming or that type changing, at the Division of  
17 Flood Management, they are tapped in with the  
18 Corps of Engineers and all the different  
19 scientific entities to continue studying that  
20 area.

21 One other point, too, the point was made  
22 about the difficult decisions for water  
23 management, do you keep the water, do you let it  
24 go. That's one of the primary reasons why when  
25 you have a multi-purpose reservoir with a federal

1 flood control reservation that the federal  
2 government has bought and paid for, that's 750,000  
3 acre feet, so they are in charge of that part of  
4 the operation, and we have very specific operating  
5 criteria to stay within their criteria.

6       If there are special circumstances where  
7 it might make sense to vary from that, we would be  
8 in communication with the Corps and they would  
9 make the call, they would make the decision. It  
10 makes sense to either up the release or do  
11 something different. That is an important point  
12 to remember.

13       MS. NEWMARK: I have one comment. I  
14 know there is a joint working group between DWR  
15 and US Bureau of Rec to look at climate change  
16 impacts on their infrastructure and operations.  
17 So, there actually is an active group, and they  
18 are actually primarily focused on the Delta, but  
19 through the CAL Sim model, of course, they include  
20 every note, every dam in the whole system.

21       Not these gentlemen, but portions of the  
22 State Water Project are actively pursuing at least  
23 looking at the impacts, if not, trying to figure  
24 out the implementation of mechanisms to address to  
25 respond to that.

1 MR. BUI: Are you referring to the CAP  
2 studies?

3 MS. NEWMARK: It is a joint working team  
4 led by Francis Chung's group, the modeling group  
5 and Lloyd Peterson --

6 MR. BUI: Okay. Lloyd Peterson.

7 MS. NEWMARK: -- over in the Bureau of  
8 the Rec --

9 MR. BUI: (Indiscernible).

10 MS. NEWMARK: (Indiscernible) -- who  
11 just moved to Denver with (indiscernible).

12 MR. BUI: Okay, to Denver, uh-huh.

13 MS. NEWMARK: Jamie Anderson. Do you  
14 know her? She is in --

15 MR. BUI: No, I don't know who Jamie is.

16 MS. NEWMARK: She is a DWR person in  
17 Sacramento, and she is involved in it.

18 MS. ZASSO: I'd like to make one  
19 comment. If there is any facility augmentation  
20 expansion on our system as one of our previous  
21 slides indicated, don't state water contractors  
22 pay for all of the bills for the operations, for  
23 maintenance, administrative costs, regulatory  
24 costs. So, anything we do as far as an  
25 augmentation to our system is coordinated through

1 them. They are certainly involved in that  
2 process.

3 MR. TRASK: I'm glad you brought that  
4 up. I wanted to get that and maybe Greg if you  
5 want to join us. I just talked with one of your  
6 co-workers about the planning process with the  
7 State Water Project people. I know you meet at  
8 least monthly on general issues, operations  
9 issues. What about your planning process, is that  
10 a regular every year, twice a year, or is it  
11 formal at all?

12 MR. JOHNSON: Yes, like I said, we have  
13 oversight involvement. Well, I wouldn't call it  
14 really oversight, a coordination would be a better  
15 word, you know, to make sure that the projects  
16 make sense economically, operation wise, water  
17 delivery wise, and that coordination is again, we  
18 would have meetings that go from weekly meetings,  
19 monthly meetings on shorter term issues all the  
20 way up to the longer term issues. A presence in  
21 all of that.

22 MR. TRASK: Like for instance, you know,  
23 there are two things that we talked about today  
24 already, your outlet there from Thermalito, you  
25 explored putting a small generator there. The

1 Coastal Branch, aqueduct, is there any sort of set  
2 process where you would like regularly reassess  
3 those kinds of things, look at what new technology  
4 is available, low head high flow, high flow, low  
5 head, that kind of thing. Is there any sort of  
6 formal process to regularly look at those kinds of  
7 things?

8 MR. QUALLEY: As part of the planning  
9 process, yeah, we are always on the outlook for  
10 new technologies, changes in the facility  
11 configuration, anything that can provide us a  
12 better more efficient operation.

13 For example, we've got a project under  
14 construction right now to build we call it  
15 Tehachapi (indiscernible), we are actually at the  
16 top of a hill, (indiscernible), we are building a  
17 small peaking storage facility up there that will  
18 allow us to take better advantage of the off-peak  
19 pumping capability of the valley strain. Right  
20 now it is constrained by the capacity of the East  
21 Branch and the capacity of Pearblossom Pumping  
22 Plant to take the flow.

23 By having that peaking storage facility  
24 up there, that will give us just enough storage to  
25 be able to hold it long enough to take more

1 advantage of the off-peak pumping capabilities.

2       We are looking for those types of things  
3 where we can make changes to the facilities, make  
4 changes to the operations, to the extent there is  
5 new technology that can be advantageous to us.  
6 That is part of our process.

7       MR. WOODWARD: A similar question would  
8 then become -- I'm not clear exactly who the  
9 entity would be, but MWD is an example, they are a  
10 big buyer of water, right? They gather --

11       UNIDENTIFIED VOICE: The biggest.

12       MR. WOODWARD: Huge, right, but my point  
13 is if you are looking for opportunities, I wonder  
14 how you are coordinating with folks like them to  
15 do the same thing, to take peaking water and store  
16 it for use --

17       MR. QUALLEY: As Craig indicated, we are  
18 in regular communication virtually all the time  
19 with like Craig works with the Water Contractors  
20 Corporation, we also work with individual  
21 contractors. There are various committees that  
22 they have. Our operating people are in regular  
23 communication. Tuan is on the phone to the  
24 especially the larger contractors on a regular  
25 basis to make sure that we have a heads up on

1 changes that are going to be made, things that we  
2 can do that would be to everybody's mutual  
3 advantage. There is a regular flow of  
4 communication.

5 Obviously the department is making the  
6 decisions and running the project, but we  
7 certainly want the input from the contractors on a  
8 regular basis, both would have the best  
9 information that is available on what their plans  
10 are and also we want to take advantage of whatever  
11 expertise is out there.

12 MR. BUI: We are constantly in contact  
13 with MWD especially. We coordinate outages, make  
14 sure that water is being delivered at the time  
15 that is least cost for them, make sure they don't  
16 take water at the time that they simply require  
17 too much on-peak pumping and so on.

18 However, if their demands are needs to  
19 be delivered, we have to deliver the water.  
20 Basically the bottom line, we coordinate with the  
21 contractors all the time just to minimize the  
22 costs.

23 MR. QUALLEY: For example, they might put  
24 a schedule in, and that would be based on their  
25 calculations, that is where they need the water.

1 Tuan and his staff would run the studies and see  
2 what the implications are, and that is where you  
3 would get back on the phone, did you realize that,  
4 do you really want to do that, do you want to  
5 tweak it a little bit, and that interaction is  
6 going on all the time.

7 MS. BURTON: You noted that the state  
8 water contractors share the costs of the State  
9 Water Project. Do they also share in the revenues  
10 from power generation? What I am driving at is,  
11 is there a way to get them to think about  
12 optimizing the power and the water as opposed --

13 MR. QUALLEY: Trust me, they are thinking  
14 about it all the time.

15 MS. BURTON: -- to worrying about the  
16 water supply.

17 MR. BUI: They are not sharing the  
18 costs, they are paying for the cost of the State  
19 Water Project, all of it.

20 MS. BURTON: Right, right, and do they  
21 get the revenue back when you generate power?

22 MR. BUI: Yes, as a form of -- I'm not  
23 well --

24 MR. JOHNSON: Like you said, there is  
25 usually a net bill for power, so it is netted out

1 against the cost.

2 MR. QUALLEY: We don't look at it as  
3 revenue, it is offsetting costs.

4 MR. JOHNSON: It offsets the costs.

5 MS. BURTON: (Indiscernible).

6 MR. TRASK: What type of planning  
7 horizons do you look at? In other words, like  
8 this new afterbay that you are putting in, what  
9 sort of pay back period or amortization period do  
10 you guys look at in your planning?

11 MR. QUALLEY: Was it ten year on that  
12 particular one?

13 MR. ZASSO: I don't recall.

14 MR. BUI: It depends on the energy price  
15 at the time that you did the study, and I forgot  
16 what it was. Ten years sounds familiar.

17 MR. QUALLEY: It seems to me that was the  
18 pay back horizon with some fairly conservative  
19 assumptions as far as off-peak/on-peak  
20 differential.

21 MR. TRASK: Is that fairly consistent?  
22 In other words, whenever you look at an  
23 improvement, do you assume it is ten year payback  
24 average?

25 MR. QUALLEY: I wouldn't say that is

1 standard. We need to look at each circumstance  
2 individually.

3 MR. ZASSO: On the maintenance side,  
4 when we are looking at facility enhancements or  
5 component replacements, we are typically looking  
6 at the life cycle of that particular component in  
7 20 years, 25 years, 30 years, and balancing that  
8 cost with the foreseeable use life of that  
9 component.

10 MR. TRASK: For instance, there is a lot  
11 really good new motors out on the market now just  
12 in the last few years. The efficiencies have  
13 really boosted up, is that the kind of thing that  
14 you look at it going that I've got this pump in  
15 place, I've paid off half of it, but there is  
16 another pump here that, you know, might even pay  
17 off quicker?

18 MR. ZASSO: Most of our equipment is  
19 fairly non-standard if you will. I mean, there is  
20 not a lot of other projects like ours in the  
21 world. At Edmunston Pumping Plant that we  
22 mentioned earlier, each unit is a 60 MW motor.  
23 There is not too many out there that are going to  
24 be able to come in and light for light replace  
25 that.

1           MR. WOODWARD: You have six of the 60 MW  
2 made anywhere in the world?

3           MR. ZASSO: We have 14 of them.

4           MR. WOODWARD: You own 90 percent of  
5 them probably.

6           MR. ZASSO: Probably.

7           MR. TRASK: A lot of our nuclear power  
8 plants have some pretty --

9           MR. BUI: They are so large that you  
10 cannot directly start them up on the grid. You  
11 have to use a motor generator to start them up,  
12 otherwise you will basically pretty much take out  
13 Fairfield. That was actually occurred twice in  
14 the history of the department. That they asked,  
15 we start it up one time, they say, hey, you guys  
16 can't do that. You have to coordinate with us  
17 first because you would power surge.

18          MR. ZASSO: On our smaller auxiliary  
19 systems, yes, that is something that is looked  
20 upon that are more standard size frame size, horse  
21 power size. When a motor burns up for whatever  
22 reason after running for 25 years, they are  
23 certainly looked upon as balance whether they  
24 repair that motor or just go buy a new one off the  
25 shelf. Most of the time, the age of some of our

1 equipment is getting, we are just replacing them  
2 right off the shelf.

3 As far as our big units. I will say our  
4 unique units, those are pretty much replaced. We  
5 may replace internal components with new and  
6 improved, but by and large, again, a lot of our  
7 equipment is fairly unique.

8 MR. WOODWARD: I am also assuming that  
9 you are trying to be high up on the efficiency  
10 curve in any event. I realize a percentage point  
11 or two with those numbers makes a big difference,  
12 but you are already in the 90 somethings on the  
13 full scale pumping I am assuming.

14 MR. ZASSO: Most of the time. In the  
15 last 10 years, 15 years, they have been going  
16 through each of the pumping plants. We are  
17 implementing a new program here for the next few  
18 years, and hopefully for the rest of the life of  
19 the project on the condition assessment program  
20 where we are going in to each particular unit and  
21 doing a wire to wire inspection of that unit,  
22 looking at ways that we can improve the life and  
23 the efficiency of those units.

24 Again, we've got some fairly unique  
25 pieces of equipment out there that we don't have a

1 lot of flexibility in changing it. Not a lot of -  
2 - when we are pumping 60 MW pump 320 CFS 2000 feet  
3 straight up, there are not a lot of other units  
4 like that in the world, 80,000 horsepower units.

5 MR. WOODWARD: Right, small ones.

6 MR. ZASSO: Small ones.

7 MR. WOODWARD: How big is a pump like  
8 that? We are sitting in a room, how big --

9 MR. BUI: It --

10 MS. ZASSO: About five stories.

11 MR. BUI: It is a four-stage pump.

12 MR. QUALLEY: 65 feet tall.

13 MR. BUI: Yeah. In this room, probably,  
14 not enough room for the unit here.

15 MR. ZASSO: One single unit probably fit  
16 with all of its (indiscernible) if you probably  
17 take this room up into a five story straight up.

18 MR. WOODWARD: Thank you. That helps a  
19 lot to get a sense of scale.

20 MR. BUI: You can walk into the about  
21 easy. You can walk into it, probably have room to  
22 spare too.

23 MR. ZASSO: Those units have been  
24 started twice as an induction motor in the life of  
25 the project as a test, not as a routine

1 operational event, but as a test. Each time  
2 Edison told us not to do that again because it  
3 does have a big influence of the grids.

4 Again, where it makes economic sense to  
5 replace with new and improved, we do that. Where  
6 it doesn't for unique pieces, we try to manage  
7 what we have, again, in coordination with our  
8 water pump directors. What makes best business  
9 sense for that piece of equipment.

10 MR. KLEIN: About the pumped storage, the  
11 capacity that is built into the system that your  
12 slide was leading to.

13 UNIDENTIFIED VOICE: You mean the  
14 presentation?

15 MR. KLEIN: Yeah, let him get done. I  
16 think that is a great idea.

17 MR. TRASK: Yeah, the presentation.

18 MR. KLEIN: Thank you for answering all  
19 of our questions. This is very very helpful to  
20 learn about this.

21 MR. BUI: The next to smallest of the  
22 three generation plants up in the Oroville Complex  
23 of the Thermalito Diversion power plants is  
24 basically located on the left abatement of the  
25 Diversion Dam. A very small unit, about 3 MWs or

1 so with a flow capacity of 615 or 620 CFS. It is  
2 primarily used for Hyatt Thermalito station  
3 service, and 3 MWs is not much at all.

4 Then there is the Thermalito Power  
5 Plant. You have both pump and gen. There is four  
6 units total. One is conventional generators, and  
7 the other one is a pump gen. Capacity is about  
8 120 or so MWs with a 17,000 CFS capacity on water.  
9 Pumping, we have three units, and about 9,000 CFS  
10 flow at the plant.

11 MR. BROOME: May I make some comments?

12 MR. TRASK: Sure.

13 MR. BROOME: I would just like to  
14 comment on the presentation and discussion we've  
15 had. I've really done my career. I am 80 years  
16 old, I am not looking for more work, however, I am  
17 concerned with what I see as underutilized  
18 investments, and I do feel that the State Water  
19 Project has done an admiral job. I have nothing  
20 but admiration for the fantastic system that you  
21 have built and operating very effectively, but I  
22 think it has a little spare capacity, in fact, a  
23 lot of spare capacity, which if either industry or  
24 the public wish to duplicate, they would have to  
25 spend a billion dollars to create.

1           You have an incredibly valuable resource  
2   that I don't think you are using to its maximum  
3   capability. I have been in conversation with  
4   several people in your office, and the last word I  
5   think I had was from Steve Kashawata. He called  
6   me some years ago, and he said, well, the reason  
7   we don't actually operate the pumping and  
8   generating plants in a daily manner, is that we  
9   really can't account for the difference between  
10   what we use in pumping and what we recover in  
11   generation, like 25 percent loss, and how do we  
12   account for that. I was left speechless  
13   because that is the situation ever other pumped  
14   storage plant that has ever been built, and it is  
15   designed to overcome that loss of power by  
16   increase in value.

17           If you look at your project from a  
18   totally different perspective, profit making,  
19   making money, then you would do it very  
20   differently. You are not there to make money, I  
21   understand that, you actually spend money to  
22   operate your system.

23           MR. QUALLEY: There is a tremendous  
24   number of constraints on the operating. Tuan will  
25   get into those a little bit more --

1           MR. BROOME: I quite understand that you  
2 do generate with whatever water you release, you  
3 know, on a seasonal basis, but the capacity that  
4 is not used is a daily money-making operation to  
5 turn cheap power into more valuable power.

6           MR. TRASK: Ken, are you talking  
7 specifically about Oroville?

8           MR. BROOME: Oroville, Thermalito, and  
9 San Luis, all three could be utilized daily in  
10 this mode. Wouldn't use any water, it is just  
11 moving it up and down. It is not in any way  
12 reducing your main mission in life, which I was  
13 interested to see didn't mention the word energy,  
14 which is a given that you use energy basically.

15          MR. ZASSO: Our main mission, the  
16 department's mission is to manage the water  
17 supply.

18          MR. BROOME: I understand that, but on  
19 the other hand, you are a custodian of public  
20 investment. The public has paid to build this  
21 plant, this whole system, and it is for that one  
22 purpose of delivering water which I fully  
23 understand.

24          MR. BUI: I appreciate your comment,  
25 Ken. Let me go through some of the constraints on

1 the system. As I go through, I will point out  
2 that there are constraints on the system. Within  
3 the constraints of the systems, we try to do as  
4 much pump back as possible as we can.

5 Let me continue that. Your comment is  
6 noted.

7 MR. TRASK: We can continue the  
8 discussion after --

9 MR. BROOME: One other thing I would  
10 like to mention is that I do understand that you  
11 are ready to provide emergency generation when  
12 necessary. The ISO operator told me on occasion  
13 he has the right to use your plants in an  
14 emergency, which is great. I think that is  
15 wonderful. On the other hand, I will say that you  
16 are missing an opportunity to make money to repay  
17 some of the debt that the public has incurred --

18 MR. ZASSO: It is being repaid by the  
19 state water contractors.

20 MR. BROOME: Yeah, I mean we suffered  
21 terribly during the power crisis in 2001/2002, the  
22 build up was huge obligation. You could recover  
23 some of that.

24 MR. ZASSO: The ISO routinely requests  
25 and makes out of market for other generation out

1 of our system. We have the right as the  
2 generator/owner to operate our system within our  
3 operating parameters, and at times have been asked  
4 by the ISO for something that we cannot comply  
5 with because it will not fit within our  
6 operational constraints.

7 MR. BROOME: Sure, no, I understand  
8 that.

9 MR. ZASSO: Again, we are dispatched by  
10 the ISO, but we will operate our system within our  
11 operating parameters and regulatory requirements,  
12 not the ISO's.

13 MR. WOODWARD: Let's let them tell us  
14 about more of the constraints. Your point is well  
15 noted, Ken, that there is potentially the ability  
16 to push water back up and let it run back down  
17 again to help generate some additional revenue, so  
18 let's see what else they are constrained with  
19 because I don't know what they are constrained  
20 with yet.

21 MR. BROOME: I did check some of the  
22 constraints, and it is important. It is not built  
23 for the purpose of just generating money. It is  
24 built for water, and there are some limitations,  
25 but the reservoir capacitors, for instance, at San

1 Luis are such that the range of head in the lower  
2 reservoir can be accommodated and maintain a  
3 constant flow in the canal.

4 In other words, there is no reason to  
5 interrupt the delivery of water in order to change  
6 the level of reservoirs at San Luis between the  
7 lower and upper reservoir, it can be done.

8 The only other thing that is missing  
9 from a typical pumped storage pump plant, is the  
10 regulating veins on the turbine, and that is  
11 because you never envision having to control  
12 frequency or voltage which typically is typical in  
13 commercial pumped storage project does, and they can  
14 claim ancillary benefits by that provision of  
15 frequency and voltage control.

16 That could be added, but it doesn't  
17 matter because they are designed for maximum  
18 generation capability which is fine, you don't  
19 have to add that, but it could be done.

20 MR. WOODWARD: No dispute that it could  
21 be, I want to hear more about what the system  
22 looks like, and we will continue the discussion of  
23 options in a little bit, okay?

24 MR. BROOME: I'm sorry, I'm a bit hard  
25 of hearing, this 80 year old.

1           MR. WOODWARD: We would like to let  
2 these folks continue the discussion that they've  
3 started, so that we can finish learning what they  
4 have to tell us today, and then we will continue  
5 the discussion of options a little bit later.

6           MR. BROOME: I do have a suggestion  
7 actually, it might even interest the businessmen  
8 here that we could overcome the problem of mission  
9 of responsibility and risk taking, all of which is  
10 a business issue. So, I can add that later.

11          MR. WOODWARD: Thank you.

12          MR. ZASSO: I appreciate it, thank you.

13          MR. BUI: Some of the constraints that I  
14 put up there are basically weekly considerations  
15 when you do your schedule, you know, generations  
16 pumping for the State Water Project.

17          The first one is water supply  
18 requirements. I am not just talking only the  
19 water supply to our own contractors. I am also  
20 talking about the water supply for the people, the  
21 voters of the afterbay also.

22          Basically the typical generations that  
23 are higher during the peak summer times are  
24 between 15,000 to 30,000 acre feet per day, with  
25 the capacity I mentioned earlier at the 30,000

1 acre feet per day, you pretty much generate all  
2 the hours available during the on-peak hours and  
3 some during the off-peak as well.

4 Another constraint we have to consider  
5 basically is the Feather River in-stream flow  
6 requirement. There are in-stream requirements  
7 that you have to maintain, (indiscernible)  
8 agreements that basically you have to maintain  
9 1700 CFS I think from October through March and  
10 then 1,000 CFS from the remainder time of the  
11 year.

12 These are changes. There are provisions  
13 in the requirement, but basically it depends on  
14 the year type, you can actually reduce those  
15 requirements. However, most of the time due to  
16 recent high flow in the system and so on, the  
17 river is kind of move, so even though the  
18 requirements let's say 1,000 CFS, people  
19 downstream (indiscernible) water to irrigate their  
20 system cannot get the water in because the river  
21 beds have moved and so on. So, we actually have  
22 to release water higher than the requirement to  
23 accommodate them downstream.

24 Water temperature requirement is another  
25 interesting animal where we have to consider

1 basically there are I can think of three  
2 requirements. The first one is the fish hatchery,  
3 the Feather River Hatchery, they like cool water.  
4 It varies, it ranges from 51 degrees to 55 degrees  
5 at different times of the year with the plus or  
6 minus about 4 degrees fahrenheit requirement.

7 We have another requirement for Robinson  
8 Riffle which is mandated that we have to maintain.  
9 This is six or seven miles downstream from the  
10 Thermalito Diversion Dam where you have to  
11 maintain 65 degrees between April to June time  
12 period in order to be in compliance.

13 MR. TRASK: That is for fisheries  
14 management?

15 MR. BUI: That is for fishery  
16 management.

17 MR. WOODWARD: They need much warmer  
18 water some of the year a little bit further down  
19 stream?

20 MR. ZASSO: Correct.

21 MR. BUI: Right. It is a different  
22 species.

23 MR. WOODWARD: It is not upstream, it  
24 would be really complicated to do.

25 MR. TRASK: That's 65 degrees maximum,

1 isn't it?

2 MR. BUI: Maximum, you cannot exceed  
3 that. This is six miles downstream, so basically,  
4 you have Kelly Ridge discharges water into the  
5 system with much hotter water. Let's say the flow  
6 is 1,000 CFS, Kelly Ridge discharges about 200 CFS  
7 of 70 degree temperatures, you basically have to  
8 scramble in order to discharge --

9 MR. WOODWARD: Lower the temperature.

10 MR. BUI: To lower the temperatures.  
11 Another temperature requirement that we basically  
12 have to meet is the rice diverter temperatures.  
13 They want warmer water during the growing season.  
14 Basically, you have two competing interests with  
15 different temperature requirements so you have to  
16 meet both of them.

17 MR. TRASK: I just want to go back to a  
18 picture of your system here to make sure I  
19 understand that. The warmer water is coming from  
20 the Thermalito afterbay, the rice growers.

21 MR. BUI: The rice growers, yes, would  
22 like to receive water in the warmer.

23 MR. TRASK: The other one that you  
24 mentioned that was 200 CFS where is that coming  
25 in?

1           MR. BUI: Kelly Ridge, it is right. It  
2 is entering right below the discharge of the Hyatt  
3 Power Plant.

4           MR. TRASK: Then you just release  
5 through the power plant, through Hyatt to mix that  
6 to meet your temperature?

7           MR. BUI: Yes, and Robinson Riffle is  
8 right about there somewhere. We have water  
9 temperature requirement here for rice grower which  
10 is warm water they desire, cooler water here for  
11 the fish, cooler water here also for the fish  
12 hatchery, and we have water entering into our  
13 system from our own facility which we have control  
14 of the temperatures.

15           We also have water from Kelly Ridge  
16 entering our system here which we have no control  
17 over. Basically it is juggling act to meet  
18 temperatures. At times, we have to bypass our own  
19 generation, especially in the dry years. When the  
20 reservoirs are down, we don't have much of the  
21 cool water pool left, and the requirements are  
22 basically right around April to June, yeah, right  
23 around that period when things start heating up.

24           You have to bypass generation, take the  
25 water right out of the bottom of the reservoir in

1 order to meet that. I believe in 2003 or 2002, we  
2 had to bypass the water in order to stay in  
3 compliance.

4 MS. NEWMARK: Do you have spillways or  
5 outlets at different elevations on the dam?

6 MR. BUI: We have intake structures that  
7 basically be able to take water at the different  
8 level, however, the system is the shutter system.  
9 Basically, whenever you take the shutter out, at  
10 that elevation is the water entering in and all  
11 the water above it. So, there is grizzly that we  
12 can put down and then make a space down there.

13 As the temperature heats up, you take  
14 shutter out, try to release the coolest water you  
15 have in the system, however, you have to kind of  
16 manage the cool water pool a little bit because  
17 otherwise if you send all the cool water out  
18 during the first early months and you run out of  
19 cool water pool, you are basically forced to  
20 bypass all the generation that you have in maybe  
21 June or July period.

22 There are a lot of things that you have  
23 to consider at the time. You have to eliminate  
24 generations, at times you have to eliminate pump  
25 back. At times you have to go and negotiate with

1 Fish and Game to make sure that water is still  
2 that's what they want. It is --

3 MR. TRASK: What are the factors that  
4 would limit your pump back?

5 MR. BUI: Temperature requirements are  
6 one of them. Economic sense is another one.  
7 Basically, you have to have enough price  
8 differential.

9 Let me go through this. The next slides  
10 will be the pump back constraints. Note the water  
11 quality and water quantity requirements in the  
12 Delta is another very very important aspect of our  
13 operations.

14 Water quality is decision 1641 by the  
15 Water Board. You have to comply by that. The  
16 Endangered Species Act, it came in the form of how  
17 much out flow you have to release into the system  
18 and how much water quality as far as electrically  
19 continuity that you have to maintain a certain  
20 station in the Delta.

21 Be it if it is water quantity that you  
22 have to release out in the river, you, in  
23 coordination with the CVP, the Bureau of  
24 Reclamation, you have to maintain the integrity of  
25 the Delta before you can export the water. At the

1 time, you have to release the water for the Delta  
2 compliance.

3 MR. TRASK: It is salinity monitoring  
4 station is dictating how you have to release?

5 MR. BUI: Yes.

6 MR. BROOME: May I ask a question about  
7 that? Is there any restriction on interchange  
8 between the Oroville Reservoir and the Thermalito  
9 afterbay? In other words, there is not fish in  
10 that section.

11 MR. BUI: Through the power canal,  
12 there's no fish. However, the Thermalito  
13 afterbay, there are elevation restrictions due to  
14 brook ponds. We put brood ponds into Oroville for  
15 water fowls. At a certain time when they are  
16 nesting season, you cannot fluctuate the --

17 MR. BROOME: You could release from the  
18 afterbay at Thermalito into the Feather River  
19 continuously without regard to the interchange  
20 between Thermalito and Oroville.

21 MR. ZASSO: We do. We release --

22 MR. BUI: We release there.

23 MR. ZASSO: -- from Thermalito afterbay  
24 through the river outlet 24 hours a day.

25 MR. BUI: Yes. Okay. Then there are

1 different times of the year basically you have  
2 flood control space like I mentioned earlier. The  
3 first three and last three months of the year we  
4 pretty much depend on the type of year we are in  
5 flood control mode.

6 Another one is afterbay elevation  
7 restrictions. These are the brood ponds of the  
8 ducks when they are migrating ducks, and they are  
9 nesting in the afterbay. It is an ideal spot for  
10 them. Once they nest, you have to stay away from  
11 flooding their nest, otherwise you are going to  
12 destroy all of the nesting there.

13 Also another species, which is the  
14 grebes, what they do is -- the brood pond is from  
15 March through June, the grebes is from July to  
16 August, so basically, you eliminate that  
17 peak season there. While the grebe is nesting,  
18 the nest of the grebes is already established.  
19 You have a elevation restriction of three feet to  
20 operate. It doesn't matter what elevation you are  
21 at, three feet, plus 1 1/2, minus 1 1/2, that is  
22 the bend of elevation that you have to work with.

23 You know, of course we optimize our  
24 generations based on the fluctuation of the  
25 afterbay, so you would release water as much as

1 you can during the week, and then bring the  
2 elevation up at the higher level, and then Sunday  
3 you don't generate because, you know, low demand.  
4 You release water from the afterbay to the Feather  
5 River in order to maintain the uniform flow.

6 If you restrict it, that elevation  
7 fluctuation you limit the ability to do  
8 pump back, do generations and so on.

9 Power requirement is another  
10 consideration we do. We have to do a lot of on-  
11 peak pumping also. Some of our power generations  
12 are to meet our own lows when the price out there  
13 is too high to purchase.

14 MR. ZASSO: It is a source for our  
15 pumping sink if you will.

16 MR. BUI: Yes.

17 MR. ZASSO: We are generating here at a  
18 pump here and moving it through the transmission  
19 grid.

20 MR. WOODWARD: Your job at that level is  
21 to minimize the cost of the pumping based on  
22 selling generation and during peak.

23 MR. ZASSO: Right, we are using our own  
24 resources.

25 MR. BUI: The next slide would show the

1 pump back constraints. When we do pump back, we  
2 basically -- there are three factors that we have  
3 to consider, economic factors. Well, the price  
4 differential between on and off peak must be there  
5 and justify the lasting efficiency and pump and  
6 gen cycle. It must be enough to justify the wear  
7 and tear on the unit itself.

8 MR. TRASK: Just to back you up there,  
9 do you know of the cost figure, what spread do you  
10 need between on-peak and off-peak?

11 MR. BUI: I don't have that figure handy  
12 with me, do you? It's been in the POC, the people  
13 that actually do the trading, they have a rule of  
14 thumb of how much differential is there to justify  
15 the loss, the difference in generations and  
16 pumping cycle and also the wear and tear on the  
17 units as well.

18 MR. TRASK: I know in general, most pumped  
19 storage you only get back between a third and a  
20 half of what you pump up, is that consistent?

21 MR. BUI: That's sounds about right.

22 MR. ZASSO: My recollection from last  
23 time that we pumped back for economic reasons. If  
24 you want to purely pump back, the differential was  
25 in the neighborhood of \$20 or more. Would that be

1 the same today, probably not. That was several  
2 years ago, but as I recall, that was the spread  
3 that we were looking at for that.

4 The temperature requirements as Tuan  
5 identified has become somewhat restricted, but it  
6 is pretty much precluded us from doing a purely  
7 economic pump back operation of the Oroville  
8 Complex.

9 I mentioned earlier of our condition  
10 assessment program that we are undertaking within  
11 our whole project. Part of that is to work more  
12 detailed at the cost of unit starts, which would  
13 again key in to what is the economic differential  
14 that we need in order to make that economic  
15 (indiscernible) operation.

16 MR. TRASK: I guess I am not quite  
17 clear. The temperature restrictions, is is  
18 because the water is actually heated up when you  
19 pump back up?

20 MR. BUI: Yeah, go back to there's a  
21 schematic I can -- the water is being  
22 pumped, being generated from here, travel on down  
23 to the Diversion Dam, on down to the power canal,  
24 entering the forebay, and then being generated at  
25 the afterbay, and then entering through the

1 pumping plant and then you know taking residence  
2 in the afterbay.

3       The compliance point is here. When you  
4 do pump back -- yeah, and up here too. When you  
5 do pump back, what happens is you are stuck in  
6 this warm water, a large amount of warm water back  
7 up this way and enter this small body of water  
8 where it mix with the cool water released from  
9 here and then travel on down to the river because  
10 this is a low flow section, you have to maintain  
11 the 600 CFS also during this stretch.

12       MR. WOODWARD: At the colder  
13 temperature?

14       MR. BUI: Yes. If you do pump back, you  
15 are bringing warm water back to this body and then  
16 mixing it with the cool water and release the  
17 water down here. So, that is where you are  
18 running into a lot of compliance problems. We  
19 found by eliminating pump back, we can better meet  
20 the compliance of this temperature station here.

21       MR. WOODWARD: The compliance is binary,  
22 either you are in it or you are not.

23       MR. BUI: Right.

24       MR. WOODWARD: If you are not, you get  
25 yelled out and fined and all sorts of other stuff

1 goes on.

2 MR. BUI: It is mandated. I don't know

3 what --

4 MR. WOODWARD: It is not pleasant to be  
5 told you are out of compliance I am assuming.

6 MR. ZASSO: The hatchery temperatures  
7 are established as part of our long term contract  
8 we've had with the Department of Fish and Game for  
9 fishery management. I believe that contract dates  
10 back to 1963. The Robinson Riffle I believe is  
11 set up through NOAH --

12 MR. BUI: I believe, yeah --

13 MR. ZASSO: Fish and Wildlife Service --

14 MR. BUI: Fish and Wildlife Service as  
15 part of a biological opinion on salmon and other  
16 fisheries in that area. That is a fairly new one  
17 over the last four or five years. So, yes, there  
18 are regulatory requirements.

19 MR. WOODWARD: It is a requirement, you  
20 don't have an option in it --

21 MR. ZASSO: No.

22 MR. BUI: No. Basically, there are  
23 options. We put chillers at the fish hatcheries  
24 in order to meet some of the temperature  
25 requirements, and we regularly have to pay

1 attention to it.

2 MR. WOODWARD: I think if chillers is  
3 the sort of stuff used for air conditioning  
4 systems, is that sort of what --

5 MR. BUI: I think it is similar to that,  
6 I don't know exactly.

7 MR. ZASSO: The chiller operation at the  
8 hatchery, it is a very small portion of the  
9 hatchery operation. The more onerous is the  
10 Robinson Riffle and the other water going into the  
11 hatchery, the hotter the water going into the  
12 hatchery, the more energy we have to use in order  
13 to get it chilled down for hatchery operations.

14 If we manage for those requirements, for  
15 both of those requirements, then --

16 MR. WOODWARD: You certainly can't push  
17 water back up to the pump. You can't head back to  
18 Lake Oroville. Either you get all the way to Lake  
19 Oroville and pray, or you stop before it gets to  
20 that pumping station. It can only go to the --

21 MR. BUI: That is defeating the purpose.  
22 You basically generate -- let's say you have  
23 limited fuel, it is a dry year, and you don't have  
24 much fuel, so you do pump back. You generate and  
25 you pump the water back so that you don't waste

1 your fuel.

2       If you cannot pump the water back up to  
3 here and pump it up into Lake Oroville, so you can  
4 generate the very next day when the power is  
5 needed and energy price are high, then basically  
6 the water is ending up right here, not much at  
7 all. The generation there is about 120 MW. Up  
8 here you have about 800 MW. So, it is designed to  
9 operate in tandem, in the pump back operation, you  
10 basically have the Thermalito pumpback travel  
11 through the power canal, put back into the  
12 (indiscernible) of the water and then from there  
13 pick up from Hyatt and put back into Oroville  
14 again. So, that is a cycle. You pump from one,  
15 and you travel it on up.

16       I have some slides that basically  
17 showing the time that more frequent that we do  
18 pump back and with less restrictions and with the  
19 restrictions that we can live with, but it is  
20 doing the first three months and the last three  
21 months of the year.

22       During the summertime, it is difficult  
23 because for one thing, if you release about 30,000  
24 acre feet through your system, you take up all of  
25 the available capacity during the on-peak hours,

1 so you don't have any room to generate in addition  
2 to what you are scheduled to release for Delta  
3 requirement, water requirement, in stream  
4 requirement, all of those requirements.

5       If you do pump back during at night and  
6 then generate at night, it defeats the  
7 purpose, you know, you have not gained anything  
8 yet, so you have to find windows in your system  
9 that allow you to do pump back, and we do this on  
10 a weekly basis, daily basis, that is what the  
11 dispatchers are for. They basically evaluate the  
12 situation and then do the planned pump back.

13       MR. ZASSO: One other facet of our daily  
14 schedule at the Hyatt Thermalito Complex is that  
15 we are also involved in the ancillary service  
16 market with the ISO. With providing both  
17 regulation up, regulation down spin, non-spin.

18       Regulation alone, we will leave a  
19 minimum amount of generation during the night time  
20 hours to be a part of that ISO market and system.  
21 We also have self-provisional requirements that we  
22 have to provide as part of pump flow.

23       The majority of our pump flows at night,  
24 so we have a set requirement that we have to  
25 comply with as far as the all the generic WECC and

1 ISO requirements for that pump flow.

2 MR. TRASK: In other words, you could  
3 take power to do pump back at night, but you  
4 actually probably need that for your pumping  
5 stations way down the line --

6 MR. ZASSO: Our ancillary services --

7 MR. TRASK: It is still probably cheaper  
8 for you to self gen and supply your own load than  
9 to --

10 MR. ZASSO: Right. Additionally, the  
11 way the Hyatt facility is constructed, there is  
12 only two pin stocks there. As far as I know to my  
13 knowledge, we don't pump and gen at the same time.  
14 We are supplying ancillary services, self  
15 complying either for us or bidding into the ISO  
16 market as part of the ancillary service, we are  
17 most likely not going to pumping at the same time  
18 and doing that. We are going to try to maximize  
19 our energy portfolio that way.

20 MR. WOODWARD: Even if you had another  
21 pin stock, you would probably still use it to sell  
22 in the ancillary market because it is more  
23 valuable?

24 MR. ZASSO: Most likely.

25 MR. WOODWARD: All right, I understand.

1 Given the constraints you've just described as  
2 going through the crook there to get back to the  
3 dam, you would almost be better off having a  
4 separate passageway that wasn't interfering with  
5 your temperature control if you were going to do  
6 more of it. You are already doing it some months  
7 of the year anyway when you are not in peak  
8 generation conditions --

9 MR. ZASSO: Right.

10 MR. BUI: As you can see, the next few  
11 slides -- can you go back to the slide --

12 MS. NEWMARK: With respect to pump back,  
13 right now you are taking warmer water and sticking  
14 it back behind Oroville Dam and the lake, right?

15 MR. ZASSO: Right.

16 MS. NEWMARK: Do you have concerns with  
17 over turn --

18 MR. BUI: Quantity is --

19 MS. NEWMARK: Quantity is not an issue  
20 because you are moving so little water?

21 MR. ZASSO: Right.

22 MR. BUI: Right. It is little water  
23 compared to the model of the lakes basically. You  
24 don't have a thermal (indiscernible) issues that  
25 you have to worry about pretty much.

1 MS. NEWMARK: Thank you.

2 MR. BUI: I mentioned the economic  
3 justification, the water temperature requirement  
4 that you have to maneuver before you can  
5 do pump back. Another one is Thermalito afterbay  
6 elevation constraints. Basically, I mentioned  
7 earlier the water fowls, the brood ponds that we  
8 put into the afterbay and also the new grebe,  
9 basically restricts that peak window that  
10 try to fluctuate the afterbay.

11 MR. WOODWARD: Again, what I am hearing  
12 is you say is it is primary summer months.

13 MR. BUI: Yes, --

14 MR. ZASSO: That is when they are  
15 migrating.

16 MR. BUI: That is when they are  
17 migrating.

18 MR. WOODWARD: You've got six months of  
19 the year where you have the ability to do a bunch  
20 of pump back and six months where you don't have  
21 anywhere near the same ability?

22 MR. BUI: Right. If you go to the next  
23 slide, basically, here is the typical Lake  
24 Oroville operations. We fill about May or so,  
25 June or so, and then we drain again during

1 September.

2 MR. ZASSO: For water supply and other  
3 regulatory requirements.

4 MR. BUI: It's a typical cycle that we  
5 operate, dry year/wet year, the lake of course is  
6 lower during the dry year, wet year plentiful. We  
7 fill it up and then we drain it.

8 There are a few elevations that I kind  
9 of pointed out. Basically right about this  
10 elevation, about 731 feet, you basically lose  
11 higher pump units. You cannot generate it because  
12 of excessive vibrations. It is out of the  
13 efficiency zone. You just don't do it. It is  
14 going to shake itself out of the --

15 MR. ZASSO: As we said earlier, these  
16 units vary with capacity, these units vary with  
17 lake elevation. We got down a couple of years  
18 ago, we got down to where a pump turbines in  
19 generate mode had a range of about 10 MWs because  
20 of the head that's on the units. We just cannot  
21 physically get anymore out of it.

22 MR. BUI: Yeah. I think it is either  
23 2002 during this period here I think it is in  
24 October of 2002 or September of 2002, that is when  
25 we actually have to use a river valve to take

1 water out of the lake. The river valve is at the  
2 regional bypass that we put it in before we they  
3 built the dam to divert that. So, we had to take  
4 the water out of the lake to supply to meet the  
5 temperature requirement, bypass generation.

6 The next elevation that I would like to  
7 point out is basically 740. We just pump turbine  
8 generation limitations. At that elevation, you  
9 are not at full capacity that you designed for, it  
10 has been derated.

11 At 750, the pump efficiencies are  
12 basically really decreasing.

13 MR. WOODWARD: They are in the 90's  
14 normally, and now they are much lower?

15 MR. ZASSO: Much much lower.

16 MR. BUI: Much lower.

17 MR. WOODWARD: The curve drops off?

18 MR. BUI: Yes, basically the curve  
19 dropped off.

20 The next -- well, this is the  
21 projection -- is this the 90 percent exceedence  
22 that you poured in here. We anticipate to fill  
23 some time in June of this year, and the cycle  
24 begins again. We are going to drain the water  
25 back down, water quality requirements, water

1 supply, instream requirements and all of that, it  
2 will drain the water back down.

3 MR. WOODWARD: The only reason you  
4 wouldn't drain down as low as if it is relatively  
5 wet through the summer, then the Delta doesn't  
6 need its salinity issues and you don't have to  
7 spend as much water keeping that up.

8 MR. BUI: Let's say it is 70 degrees in  
9 Los Angeles or the Central Valley. Basically, we  
10 have the water to delivery. If we don't have  
11 demand, basically, it is going to stay in  
12 Oroville.

13 We try --

14 MR. WOODWARD: If it gets to 90 degrees,  
15 we all have trouble, and you've got to start  
16 shipping water.

17 MR. BUI: Lawns need to be watered.

18 MR. ZASSO: Crops need to be irrigated.

19 MR. WOODWARD: Yeah, I'll go for those.  
20 That lawn thing, I'm not sure I want to agree with  
21 yet, but I'll accept that is the current demand.

22 MR. BUI: The next slide will show  
23 basically, this is a 2000 -- I didn't have time, I  
24 put this in rather quickly. I should have done  
25 some recent year as far as pump back pattern.

1 This is 2000 of the Oroville Complex pump back  
2 operations. I don't know if you can see there is  
3 a blue and a magenta. The blue is a higher pump  
4 back, and the magenta is basically Thermalito. As  
5 you can see, they are designed to operate in  
6 tandem.

7       So, like I mentioned earlier, during  
8 this period here, we tried to find windows of  
9 opportunity to do pump back as much as we can, but  
10 the majority of the time that we do pump back  
11 during the last three months of the year and the  
12 first three months of the year, basically winter  
13 and then fall. Those are the periods --

14       MR. TRASK: Can you explain what  
15 happened in June there?

16       MR. BUI: I don't know what happened in  
17 June there.

18       MR. ZASSO: My guess, and it is a guess  
19 either that was a system disturbance that  
20 precluded us from moving energy from north to  
21 south, and instead of selling it off for pennies  
22 on the MW, we most likely within our temperature  
23 requirements and operational requirements probably  
24 put some pumps on to use our energy that we had  
25 already acquired and was most likely bringing in

1 through from the Pacific Northwest.

2 MR. WOODWARD: That was actually the  
3 window between the grebes and the riffles, right?

4 MR. ZASSO: Yeah, pretty much.

5 MR. WOODWARD: One vacated, and there  
6 was a couple of days of movement --

7 MR. ZASSO: If you notice, it was very  
8 short duration too.

9 MR. BUI: Yes, very short. I mean it is  
10 probably a couple of days there or something.

11 MS. PARK: How come that is funny?  
12 That's June 2000, that was the start of the  
13 California (indiscernible) --

14 MR. QUALLEY: That is when they had the  
15 spike where the generators were testing.

16 MR. BUI: Even with a high price, you  
17 really, you know, can't do it during this period.  
18 There is too much constraints --

19 MR. TRASK: 2001 was fairly similar?

20 MR. BUI: Similar, yeah, it is probably  
21 similar. If you have a lot of releases out of the  
22 system, then basically you are running out of your  
23 capacity window during the on-peak hours to  
24 generate, you know.

25 The next slide I believe that is I am

1 turning it over to Tio, and Tio will go over the  
2 San Luis Joint-Use Complex, so here you go Tio.

3 MR. ZASSO: Again, our San Luis facility  
4 is a joint-use facility. It is co-owned by the  
5 department of the Bureau of Reclamation. That  
6 includes generally pumping and generating plants,  
7 San Luis Reservoir and O'Neil Forebay. Also Dos  
8 Amigos Pumping Plant and also the California  
9 Aqueduct between pools 14 through 21.

10 The San Luis Reservoir itself is roughly  
11 around 2 million acre feet with the DWR share just  
12 a little bit over a million acre feet. The Bureau  
13 is about 965,000 acre feet.

14 The pumping generating plant was  
15 designed and constructed by the Bureau of  
16 Reclamation. It was completed in 1967, and again,  
17 we operate it in coordination with the Central  
18 Valley Project operations of the Bureau of  
19 Reclamation.

20 It is the primary facility for moving  
21 water in and out of San Luis Reservoir for both  
22 this SWP and the CVP operations.

23 When water is moved from San Luis  
24 through Gianelli to O'Neil Forebay, that is where  
25 the California Aqueduct begins again is in O'Neil

1 Forebay. For federal contractors and pools 14  
2 through 21 and our state water contractors, we  
3 move water through up the California Aqueduct.  
4 Additional water, especially in the  
5 summertime in the peak, is moved through the  
6 Bureau owned O'Neil Pump gen plant back into the  
7 Delta Mendota Canal. We are actually providing  
8 water from San Luis to the California Aqueduct for  
9 both federal and state contractors and to the  
10 Delta Mendota Canal for federal contractors.

11 MR. WOODWARD: Can we go back to this  
12 map of the state, so you can point to that. Thank  
13 you, I'm just somewhat clueless on where all of  
14 these things are, so it helps.

15 MR. ZASSO: Okay. San Luis is right  
16 here. This is the California Aqueduct. In this  
17 section of the California Aqueduct, it is a joint-  
18 use canal. There is both federal and state water  
19 co-mingled. All the turn outs for agricultural  
20 users in this stretch are primarily all federal.  
21 We don't have any turn outs for the state.  
22 The state picks up downstream here. This is all  
23 state from here on out.

24 In this stretch right in here, there is  
25 a parallel canal, the Delta-Mendota Canal which is

1 all federal. Her is San Luis right at the apex of  
2 San Luis and the aqueduct is O'Neil forebay. That  
3 is the main transfer body if you will. It is  
4 about 40,000 some acre feet. Water from the Delta  
5 here is moved into O'Neil. The Bureau can't pump  
6 up into O'Neil or generate from O'Neil into the  
7 Delta-Mendota Canal.

8 In fact, how the Bureau fills their  
9 share of San Luis is that they pump from the Delta  
10 through Tracy Pumping Plant, through the Delta-  
11 Mendota Canal, and then pump up into O'Neil  
12 through the O'Neil Pump/Gen Plant, and then we  
13 take it from there using their share of San Luis  
14 of the Gianelli Pump Gen Plant.

15 We will be moving again in the peak time  
16 of the year. We are going to be moving water from  
17 San Luis, not only the feed demands along the  
18 California Aqueduct but also augmenting the  
19 demands on the Delta-Mendota Canal. It is not all  
20 of the Delta-Mendota Canals demands, but it is a  
21 good portion of it.

22 MR. TRASK: Is the Delta-Mendota  
23 larger --

24 MR. ZASSO: No, it is smaller.

25 MR. TRASK: Okay.

1       MR. WOODWARD: That ultimately goes to  
2 the CVP which runs down the east side of the  
3 valley --

4       MR. ZASSO: Correct.

5       MR. WOODWARD: Okay.

6       MR. ZASSO: Does that answer your  
7 question?

8       MR. WOODWARD: Thank you, very helpful.  
9 I just didn't know where we were talking about.

10       MR. ZASSO: The slide says San Luis PGP  
11 yearly operation, the next one. We have basically  
12 two modes that we operate San Luis in. Part of  
13 the year we are in -- from mid April to late fall,  
14 facilities operate in generate mode, delivering  
15 water from the reservoir for both DWR and the CVP.

16       Mid April historically begins Delta  
17 export curtailments. There is not a lot of water  
18 in the Delta, we've still got demand, that is when  
19 our demand starts picking up. It will add San  
20 Luis water in with our Delta water coming in for  
21 delivery to state water contractors.

22       Typically, we will generate between  
23 10,000 to 20,000 acre feet per day during the peak  
24 summer months with some off-peak generation needed  
25 to meet water supply deliveries. We have certain

1 operational ranges within our canal, but the level  
2 of demand that we have, especially in the peak  
3 time of the summer we are going to be filling up  
4 our on-peak generation for both us and the Bureau,  
5 Central Valley Prop Project, and most likely  
6 generating into some of the shoulders and  
7 potentially into the off-peak in order to meet  
8 those deliveries.

9       The maximum we've ever delivered out of  
10 San Luis Reservoir for both projects combined is  
11 in excess of 20,000 acre feet, and that was  
12 several years ago. We moved 2.3 feet out of San  
13 Luis in one day. That was 23,000 acre feet and  
14 change. That is a lot of water, and that was  
15 pretty much around the clock. There was no room  
16 from pump back at all during that period. We were  
17 filling up generation only.

18       MR. WOODWARD: TAF is 1,000 --

19       MR. ZASSO: Thousand acre feet.

20       MR. TRASK: Not trillion.

21       MR. WOODWARD: I just wanted to know  
22 what the "T" stood for.

23       MR. TRASK: Tio, during that time, I  
24 would assume then that the actual water coming  
25 down to San Luis was --

1 MR. ZASSO: Minimal.

2 MR. TRASK: -- very cut back, okay.

3 MR. ZASSO: Minimal. Rate fault mid

4 April. The facilities operated in pump mode.

5 Again, we are trying to fill San Luis each year

6 the water supply. Not only for the State Water

7 Project, but for the Central Valley Project as

8 well. So, we are taking it down to a minimum, say

9 300,000 or 200,000 acre feet and trying to get

10 back up to 2 million acre feet by mid April.

11 MR. WOODWARD: That is sort of on-peak

12 and off-peak pumping if you will, very seasonal.

13 MR. ZASSO: Very seasonal if you will,

14 yes. The water is there. If we don't have demand

15 for it, the water is available in the Delta to

16 move, we are going to move it and park it in San

17 Luis. Again, that's for future water supply.

18 Next slide please. At Gianelli we have

19 the facility as constructed with four pen stocks

20 with two units for each and water is either pumped

21 or generated between San Luis and O'Neil forebay

22 as we discussed. It is connected to the grid at

23 Los Banos sub with two 230 KV lines.

24 There are eight pump turbines there.

25 They are all francis type. They are dual rotor

1 design, which means they actually have two  
2 rotating rotors up there. One stater, and they  
3 will either run at 120 RPM at lower reservoir  
4 levels or at either 150 or 156 at higher reservoir  
5 levels.

6 The gentleman was correct earlier, there  
7 are no governors on these units, they are either  
8 on or off, actually the shut off from the  
9 reservoir are butterfly valves. They are either  
10 on or off. There is no -- we do not provide any  
11 regulation up or down or any spin at these units  
12 either. We do bid in occasionally, do bid non-  
13 spin in at San Luis because then we can dispatch  
14 that ourselves.

15 MS. NEWMARK: What are the nominal head  
16 differentials or the elevation differentials  
17 between these two bodies?

18 MR. ZASSO: Let's see, that's a good  
19 question. Max elevation at San Luis is about 500,  
20 and I am thinking --

21 MR. BUI: Yeah, I am thinking about in  
22 the neighborhood of 300 --

23 MR. ZASSO: -- about 300 feet of  
24 differential.

25 MR. TRASK: How quickly can you crank up

1 generation?

2 MR. ZASSO: Within ten minutes. Non-  
3 spin requirement, I believe we have to have the  
4 unit on line within ten minutes I think.

5 MR. TRASK: To maximum power.

6 MR. ZASSO: Yeah. The two units that  
7 have the 156 RPM rotors installed are actually our  
8 high head units, and those are used for increase  
9 pump efficiencies at the higher reservoir levels  
10 for fill operations. I will have a slide later  
11 that will go through the numbers on  
12 efficiencies throughout the range of the  
13 reservoir. Again, as with high head, they vary  
14 with reservoir level.

15 There are some operational limitations  
16 for mode changes from generation to pump or pump  
17 to generation. It is approximate one hour each  
18 mode change to reconfigure the bus electrically  
19 and to allow the motor generator windings to cool.

20 Over the last five or six years, we've  
21 had an on-going program at Gianelli inspecting our  
22 motor straps. We had a failure back in 2000 on  
23 one of our units to where a strap came loose and  
24 it basically torched the unit for almost a year  
25 while the redesigned the strap arrangement and

1 came in with modifications. So, we have been  
2 systematically inspecting our straps and as annual  
3 maintenance outages, which I am involved in, in  
4 setting the time for operations going through and  
5 making repairs and design changes on those units.

6 MR. TRASK: You have to physically  
7 reconfigure your switch gear?

8 MR. ZASSO: The operators have to go in  
9 and change, to go from one mode to the other, yes.  
10 Whether it be mechanically or remotely, they can  
11 do both, but they still have to some time to do  
12 that.

13 At certain reservoir elevations,  
14 changing from mode from either pump to gen or gen  
15 to pump may require a rotor change as well. There  
16 is a certain range around mid reservoir level to  
17 where in one mode you will be in the 150 or 156  
18 RPM, and the other mode you will be in a 120. It  
19 is just a characteristic of the particular units.

20 Next slide please. This is a cut away.  
21 Again, the old name was San Luis Pump Gen when it  
22 was designed back in the 60's. Again, here shows  
23 the dual-rotor configuration. The pump set center  
24 line here is roughly around 200 feet, and then is  
25 here the discharge or the shut off valves here.

1       The next slide please. This shows our  
2   yearly cycle, very similar to what you saw for  
3   Oroville. Again, we are always trying to top it  
4   off by mid April. We historically have Delta  
5   curtailments that begin in the spring time that we  
6   are limited from moving water from the Delta. So,  
7   we are always trying to target 2 million acre feet  
8   for both projects.

9       At that time --

10       MR. TRASK: You are very consistent it  
11   looks like.

12       MR. ZASSO: That is our target. This is  
13   water supply. This is water supply for 20 million  
14   Californians and 900,000 acres of farm land in the  
15   Central Valley.

16       MR. TRASK: Compare it to your  
17   operations in Oroville, which were variable season  
18   to season, even in dry years, it looks like you  
19   are able to fill San Luis or almost fill it in  
20   every year.

21       MR. WOODWARD: You don't have a choice  
22   if I am understanding right.

23       MR. ZASSO: That's correct.

24       MR. WOODWARD: This is the requirement  
25   of supply in the water?

1           MR. ZASSO: That's right. If work  
2   curtailed out of the Delta, this is our next  
3   supply.

4           MR. BUI: Right. The reason you see is  
5   April period. We try to top it off like Tio said  
6   earlier. During April and May period, we have  
7   what we call vamped curtailment, it is  
8   (indiscernible) Adopted Management Program.  
9   Basically that is when the fish are migrating out  
10  to the ocean, so basically what they want us to do  
11  is curtail our pumping, provide extra flow to the  
12  system, so to help the fish migrating outward.

13          MR. WOODWARD: To leave.

14          MR. BUI: To leave exactly, a fish  
15  flush. So, we cut the pumping down in compliance  
16  with this program, then the other water supplies  
17  are basically at the same time water demand is  
18  picking up, so we supplement whatever we can pump  
19  out of the Delta, the water out of San Luis. So,  
20  you see right around April 15 to May 15, that is  
21  when the curtailment period, that coincides with  
22  the period that when San Luis is actually  
23  draining.

24          MR. ZASSO: Right. Again, certain years  
25  we hit it harder than others. This is probably

1 typically a fairly wet year when there was extra  
2 water in the Delta, we didn't have to take it down  
3 as far. If you will notice, it is still similar  
4 curve, we are still -- we are maximizing our  
5 exports from the Delta as we are allowed to and  
6 augmenting it with deliveries out of San Luis.

7 I plotted some of the basic  
8 elevation curves here. At maximum, we get about  
9 50 MWs a unit, 2100 CFS, gen, and then in the pump  
10 mode spurring that MW 750 CFS, that is why we have  
11 those two units configured for 156, pumping the  
12 other six units are very very -- the efficiency  
13 really goes down at the higher elevations. As you  
14 can see, those are almost double. It is 1600 CFS  
15 for those two units.

16 If you can pull the slide back a little  
17 bit and give you an elevation look. That  
18 is around 540 foot elevation. At 500, you are  
19 looking at about 40 MW, 1900 a piece, 45 and 1650.

20 Pumping wise, you are looking at 55 MWs  
21 for two units and 45 for the other six. We can  
22 generate with about 40. We have to use 445 and 55  
23 MWs to pump with. That is just a characteristic  
24 of the unit.

25 At 450 for the elevation, all the

1 units -- again, we've had a rotor swap, and we are  
2 now in the 120 rotors, so you get about 30 MWs a  
3 piece, 1800 CFS. Pumping is about the same 1555.  
4 For 100 feet, we are down to 20 MWs, 350 feet,  
5 which we haven't gotten to in many years, but we  
6 did get down to the 400 foot back in '04. We are  
7 down here about 10 MWs. Again, it is a very very  
8 constant cycle throughout the year.

9       We try to maximize the Delta filling up  
10 by the early spring. We are using it for water  
11 supply for both the Central Valley and for  
12 Southern California.

13       MR. TRASK: How long does it take you to  
14 change a rotor out?

15       MR. TRASK: To swap rotors? We  
16 typically schedule that about an hour. Again, the  
17 same time. At the same time if they are going  
18 from pump to -- if they need to go from pump to  
19 gen, then that will be part of that same activity  
20 for that particular hour.

21       MR. TRASK: In emergency situations,  
22 they can swap faster than that, but we typically  
23 schedule that to allow the operator time to swap  
24 the systems down. That is still one of our manned  
25 plants. We do have some remote operated

1 facilities. This is still one of them that is  
2 manned. It also allows, again, all the windings  
3 and everything the coal before we swap to the  
4 other mode.

5       Going from pump to gen usually isn't the  
6 problem, it is going from gen to -- a fraction  
7 going from pump to gen is usually the more onerous  
8 one we have to let the windings cool a little bit  
9 more for that. Going the other way, generator  
10 tends to pretty cool in that mode.

11       MR. KLEIN: On this chart on the left  
12 side, it looks like at the different reservoir  
13 elevation levels, the generation capacity goes  
14 from 2100 CFS to 1900 to 1800, 1550, and 1100, but  
15 the pumping capacity seems to vary in a very  
16 different way.

17       MR. ZASSO: Yes, it does.

18       MR. KLEIN: That would effect the  
19 economics --

20       MR. ZASSO: Yes, it would.

21       MR. KLEIN: -- of your pump back  
22 opportunities quite a bit.

23       MR. ZASSO: Again, right in here you've  
24 got somewhere in this range in here, you've got a  
25 rotor change. The units do not like, especially

1 at the lower elevations, do not like to run in  
2 that 150/156 RPM range. It vibrates the unit,  
3 cavitates the units, we don't like to operate them  
4 in that mode. We have to go to the 120 rotor.

5 MR. TRASK: The vibration comes from the  
6 cavitation.

7 MR. ZASSO: And that lack of head. At  
8 this level trying to pump with, there's not a lot  
9 of head there. Any questions? Next slide please.

10 In conclusion, that is all I have on the  
11 San Luis facility. I would like to say one thing  
12 that when we are delivering for both the CVP and  
13 the SWP as I said before in certain times of the  
14 year, we are generating all the on-peak hours, we  
15 are generating most likely some if not all the  
16 shoulder hours, and potential even in to the on-  
17 peak to make sure that we can meet deliveries and  
18 operate our system within the normal operating  
19 criteria and requirements that we have.

20 MR. WOODWARD: That's the whole system,  
21 not just San Luis?

22 MR. ZASSO: Right, we operate the ditch  
23 every day within -- each pool has its own  
24 operating range. Each reservoir has its own  
25 operating range, each plant has its own operating

1 requirement.

2 MR. CROOKS: Excuse me, when you say  
3 they are operating at full capacity during all  
4 peak hours, is that what you said?

5 MR. ZASSO: For generating water from  
6 San Luis into O'Neil for delivery, we are going to  
7 fill up all the day time hours.

8 MR. CROOKS: I guess what I am referring  
9 to is where you said that I think you said  
10 generating on on-peak hours, generating  
11 electricity on all on-peak hours --

12 MR. ZASSO: At San Luis.

13 MR. CROOKS: Is that at full capacity?

14 MR. ZASSO: Typically, when we are doing  
15 that -- if you can go back to the slide of the  
16 reservoir level -- we are looking most of the time  
17 our peak deliveries are June, July, August. If  
18 that is April, we are looking somewhere in here,  
19 so we are typically not at full capacity when we  
20 are hitting our peak delivery time. That is the  
21 nature of our demand pattern downstream.

22 Our upstream supply is curtailed, our  
23 downstream requirements are going up. So, we are  
24 moving water in this period. So, if you are  
25 looking at June, July, August, you are typically

1 in this period right in here. So, we are down  
2 somewhat. We will fill up as the capacities come  
3 down, we will be filling up all of those hours as  
4 we need to.

5 MR. CROOKS: You dispatched it all based  
6 on price in the market. Is there a price forecast  
7 function within the department, and is there any  
8 dispatch on market price signals?

9 MR. ZASSO: There is. We will most  
10 likely tie that in to our ancillary bids,  
11 especially at San Luis. Again, we can't do any  
12 regulation of spin because of the nature of the  
13 characteristics of the units. We may have a non-  
14 spin bid in there for "X" amount at a certain  
15 market price.

16 MR. BUI: We don't have a grouping  
17 department for new forecasting, price forecasting,  
18 if that is the question you were just asking. We  
19 contract with other entities to provide us with  
20 the price forecast.

21 MR. JOHNSON: Maybe I can add. What is  
22 being done is that you are optimizing in this case  
23 as you are trying to minimize the net power cost  
24 over the year within the constraints of the water  
25 delivery. When you get to the San Luis Reservoir,

1 there are tighter constraints there than you would  
2 see at the Hyatt where you have the large  
3 afterbay. So, Tuan spoke about it earlier, there  
4 is a weekly pattern of releasing from Oroville  
5 into Thermalito so you get your generation in the  
6 on-peak hours, but then you have your cost and  
7 flow out of the afterbay into the river. That is  
8 an optimization there to get the maximum benefit  
9 from there. You are maximizing your on-peak  
10 generation and still have a constant out flow from  
11 the entire project.

12 When you get down to San Luis, you don't  
13 have that large of an afterbay and those other  
14 tighter constraints on that, that can limit what  
15 you can do.

16 MR. ZASSO: Our California Aqueduct has  
17 an operating range of around one to two feet per  
18 day, and at peak time of the year, you know, we  
19 are going to be moving. Peak month out of San  
20 Luis, we will move a half million acre feet. That  
21 is all going somewhere. It is either turn outs  
22 out of the California Aqueduct or downstream  
23 terminal reservoirs down in Southern California.

24 The bulk is coming out of turnouts along  
25 the California, so we've got to meet our demand

1 targets, identified by our water contractors and  
2 our users. We have to replace our water mostly on  
3 a daily basis because we have such a small  
4 operating range on the canal. That is, again, as  
5 we said earlier, that is to protect the integrity  
6 of the canal.

7 MR. TRASK: The canal just flows right  
8 into and right out of the forebay, there are no  
9 gates or anything --

10 MR. ZASSO: There is a gate structure  
11 there.

12 MR. TRASK: There is gate structure. In  
13 general, as you fluctuate the forebay, you are  
14 also fluctuating your canals.

15 MR. BROOME: Does the Bureau have any  
16 say so as to how you pump or generate at San Luis,  
17 or is it strictly a state decision?

18 MR. ZASSO: No, they have say so. They  
19 provide what schedule they would like each on a  
20 daily basis on a pre-schedule basis. Say today  
21 they are giving us what their schedule will be two  
22 days from now for the next couple of days after  
23 that.

24 MR. BUI: Basically, they fill up their  
25 share, and if they don't use all of their share,

1 we have the opportunity to use the capacity  
2 available. Basically, it is a correlation between  
3 the two projects. Our control rooms are basically  
4 separated by a door. You know --

5 MR. WOODWARD: It makes sense.

6 MR. ZASSO: Again, during the peak  
7 delivery time of the year, June, July, August, you  
8 know, they are using their percentage, we are  
9 using our percentage. We are filling up most of  
10 the day with generation to meet deliveries.

11 MR. TRASK: When you release, you are  
12 just releasing at your maximum rate all the around  
13 the clock. You can't release more during the day  
14 and less at night?

15 MR. ZASSO: We are filling up the day  
16 time hours at a rate, and we may shut particular  
17 units off at night if we need to back off a little  
18 bit. During the summer months, we are running the  
19 plant pretty hard.

20 MR. BUI: Tio, you mentioned about the  
21 limitation of number of stop at San Luis.

22 MR. ZASSO: Again, as I alluded to, we  
23 had a failure a few years ago of one of the  
24 (indiscernible) straps that burned up one our  
25 units. We are very cognoscente about the number

1 of pump starts that we have on those units.

2       During the fill time of the year, around  
3 this leg up in here, we will interrupt the day  
4 time, we will interrupt the unit for a day and let  
5 our maintenance staff get in there to do a  
6 fluoroscope and visual inspection on the  
7 (indiscernible) straps and make repairs if  
8 necessary. Last year I think we made repairs on  
9 two units during the course of our fill cycle  
10 here, which eliminated a potential catastrophic  
11 event. We are very cognoscente of the number of  
12 pump starts that we put on those units.

13       It is a water start. The units were  
14 designed originally for unwatered start, again,  
15 system design by the Bureau years and years ago  
16 and never worked, so the units were watered up or  
17 started up in pump mode watered up. So, it is  
18 very hard on the units.

19       MR. TRASK: You need motor generators  
20 here as well to start them up?

21       MR. ZASSO: (Inaudible).

22       MR. TRASK: No, you don't, okay.

23       MR. ZASSO: Breakers close, they start  
24 rolling.

25       MR. TRASK: And watch the lights go dim.

1           MR. WOODWARD: We have several questions  
2 here, Matt, and we are sort of at a lunchish time,  
3 but --

4           MR. TRASK: I was just going to say  
5 that, we are at 12:30.

6           MR. WOODWARD: I don't want to lose our  
7 folks from DWR. I suspect they actually only  
8 committed the morning to us, but we have some  
9 other questions that we would like to consider  
10 today, so if one or more of your able to stay, it  
11 would be very helpful even after a lunch break.

12          Otherwise, we ought to proceed.

13          MR. TRASK: I'm open as far as you're  
14 open.

15          MR. BUI: He drove here, so I am kind of  
16 like a passenger.

17          MR. WOODWARD: Let me recommend that we  
18 take a lunch break.

19          MR. TRASK: I like that recommendation.  
20 Can we do it in an hour? Off the record.

21          (Whereupon, at 12:33 p.m., the workshop  
22 was adjourned, to reconvene at 1:45  
23 p.m., this same day.)

24                   --oOo--

25

1 AFTERNOON SESSION

2 1:45 p.m.

3 MR. TRASK: We are now official again.

4 Somebody just joined us on the telecom. Who is  
5 there?

6 MR. PARKER: James Parker.

7 MR. TRASK: Hi James, how are you doing?  
8 Matt Trask. We are just going to finish up here  
9 our discussion of State Water Project operations,  
10 specifically related to power generation. I guess  
11 I will just throw open the floor. I will note  
12 that in the study, the water energy relationship  
13 study, I was largely silent on pumped storage and  
14 other water system generation possibilities,  
15 largely because I only had a few months to pull it  
16 together, and I didn't think we could get any  
17 projects built in that time.

18 This could be the start of a longer term  
19 I guess at least a discussion group if not  
20 actually a policy planning group. If anybody is  
21 going to lead that, it is probably the two  
22 gentlemen up here at this end of the table since  
23 it is their baby, and they are actually Energy  
24 Commission people.

25 Gary, did you have any comments or

1 questions?

2 MR. WOODWARD: I want to thank everyone  
3 for this morning's discussion. I learned a ton of  
4 things and put a lot of thoughts into perspective,  
5 and that is very valuable. I don't know where we  
6 are going to go exactly on this specific question  
7 of pumped storage, but I do know as a state, we are  
8 looking for a way to store intermittent energy  
9 sources. Sun and wind sort of come to mind.

10 In relatively large quantities, we are  
11 talking about 10,000 MWs or more worth of the  
12 stuff.

13 MR. BROOME: How much --

14 MR. WOODWARD: About 10,000 ultimately  
15 sort of the rough numbers we are looking at in  
16 broad brush strokes about 4,000 MWs of wind in the  
17 Tehachapi area and the solar folks for large scale  
18 solar are starting to come out and talk with us,  
19 and there are several thousand MWs in the Mojave  
20 area. There is also a discussion putting  
21 geothermal on line down in Imperial Valley. That  
22 is a lot less intermittent if you will, but it is  
23 the intermittent sources that we really have to  
24 start thinking about.

25 So, to the extent that we are putting

1 that much on line, we would like to be able to  
2 soak some of its energy if you will when it is  
3 available and do something useful for the state.  
4 One of the obvious things is storage.

5 With that in mind, if the State Water  
6 Project doesn't necessarily represent the majority  
7 of the opportunity, all right. Don't feel bad  
8 here, we are all part of the same picture. We are  
9 trying to figure out where we ought to go focus  
10 our attention and help it happen.

11 We are basically for you all to put your  
12 feelers out and see who else do you know, whether  
13 it is your folks or others. We might have some in  
14 the way of storage. If it is storage water and it  
15 happens mean more flood control, super. Let's get  
16 threefords and fourfords out of project, right, it  
17 makes it pay better. We are sort of putting  
18 feelers out to see what's out there at this stage.

19 MR. TRASK: Yeah, Laurie with Hetch  
20 Hetchy, I know you have two reservoirs above Hetch  
21 Hetchy, there is no way to pump up to those, is  
22 there?

23 MS. PARK: (Inaudible) -- is a proposed  
24 pumped storage project at Cherry Eleanor. Basically  
25 what happens is because of the make up of the

1 water sheds that serve the systems, the left side  
2 and the right side are about equivalent in  
3 capacity of reservoir, but the water shed on the  
4 Hetch Hetchy side is more than three times the  
5 size of the water shed on the Cherry Eleanor side,  
6 with the result you tend to fill and spill in  
7 average years 2 1/2 to 3 times on the Hetchy side.  
8 On the Cherry side you have a risk of not filling.

9 Both for water supply and for summer  
10 peak pumping, for peak generation purposes, we had  
11 looked at taking some water out of the river on  
12 the Hetchy side, moving it back up the hill. They  
13 happen to converge right conveniently at the  
14 perfect point. Moving it back up the hill to  
15 Cherry, the problem is we are under -- I keep  
16 saying we. Hetch Hetchy is under Department of  
17 Interior permits. They are operating on federal  
18 lands, and there are some real complications to it  
19 because one of the arteries, the artery that home  
20 power house comes out of and discharges into  
21 (indiscernible) Scenic River, so there are many  
22 many challenges.

23 I mean there are opportunities like  
24 this. This would be a really valuable resource,  
25 but the hurdles to it are considered to be so

1 onerous that it just continues to sit on the books  
2 as a good idea.

3 MR. TRASK: Virtually anywhere you  
4 already have a reservoir, you could always add,  
5 even if it is only a tank, you could put in some  
6 micro-hydro pumped storage, but I guess what is  
7 missing, what I haven't seen anywhere is how could  
8 you analyze that from over the lifetime of a  
9 project. What does it cost to add pumped storage to  
10 an existing reservoir, what are you going to get  
11 out of it, especially with the variability and  
12 precipitation.

13 MS. NEWMARK: Matt, this is a study that  
14 one of my colleagues did last year. It's title is  
15 "Increasing Pumped storage in California by Linking  
16 Existing Reservoirs." This is a very high level  
17 GIS base. Look at pairs of reservoirs, and there  
18 are tables in the back where they are looking at  
19 El Pardo Comanche, and you will go through at  
20 (indiscernible), turbine cost, pipe cost using  
21 only public access, no private permit. Of course  
22 the line links are probably not optimized, but  
23 they are a good start and an idea of generation  
24 and cost per KWh.

25 It is a very course assumption, but it

1 went through and looked at a lot of potentials in  
2 our system, so I can give you a copy of that.

3 MR. TRASK: Great, yeah.

4 MS. NEWMARK: It is nowhere near the  
5 level of detail necessary that, for example, as we  
6 have learned, the constraints on actually  
7 operating in these systems that any of the  
8 operators know about, you have water release,  
9 you've got your turbidity which you don't have,  
10 but Hetch Hetchy has issues with turbidity.

11 They are all other parameters  
12 that would need to be assessed, but this is sort  
13 of a first cut at where the reservoirs, what are  
14 the lanes, what ball park are we talking  
15 about. It is actually compelling gross --

16 MR. TRASK: Right, but as you say, it is  
17 a good start. I haven't seen anything really.

18 MS. NEWMARK: I can send you  
19 electronically, but I might have it on my machine  
20 here. I can get it to you.

21 MR. QUALLEY: There was a project that  
22 you mentioned in the white paper. I don't really  
23 know anything about it, I was fascinated,  
24 the one down at Lake Elsinor where the water  
25 district is trying, and I guess they are in the

1 process of trying to get a FERC license for that.  
2 It seems pretty ambitious to get through all the  
3 regulatory hurdles on that one in that particular  
4 area, but more power to them if they can I guess.

5 MS. NEWMARK: Again, one of my  
6 colleagues had the idea of the expansion of Los  
7 Vallequeros Reservoir as an opportunity for this,  
8 and there is actually a gentlemen who has been  
9 talking to (indiscernible) mother's uncle I guess  
10 about it.

11 They identified a small canyon that is  
12 public access. I think it is within the water  
13 shed in Contra Costa Water District that it has  
14 the right capacity, and they looked at it as a  
15 potential. When you look at the Cal Fed expansion  
16 of Los Vallequeros, that might be an opportunity.

17 Of course, anybody who has to deal with  
18 just permitting Los Vallequeros doesn't want to  
19 deal with, oh, we will flood another little area.  
20 It takes a lot of intestinal fortitude I think to  
21 go forward with one of these projects, but it was  
22 an external driver to recognize the benefit of  
23 (inaudible).

24 MS. BURTON: The other part to that is  
25 (inaudible) --

1 MS. NEWMARK: Right. I'm sorry.

2 MS. BURTON: -- (inaudible).

3 MS. NEWMARK: It is in proximity to the  
4 intermittent source was excellent for that.

5 MR. TRASK: In my opinion, if we are  
6 going to get to a 30 percent renewable, we have to  
7 find some storage somewhere. There is just no  
8 other option.

9 MS. PARK: We have been talking about  
10 pumped storage, but one of the topics that I have  
11 not seen covered well has been the issue of  
12 repowering. You know, when we get into  
13 repowering, we get into the issue of RPS, which  
14 is, you know, a lot of the great untapped  
15 potential that we have right now are aging power  
16 plants, hydro plants where they could be upgraded  
17 and they could actually produce more, but there is  
18 a clear disincentive to do so because that  
19 incremental repowering if it pushes over the 30 MW  
20 limit does not qualify for RPS.

21 At Hetchy, we were blessed because we  
22 had a very creative engineer who was constantly  
23 trying to push the limits of what we could get out  
24 of the system, and through what he called tweaking  
25 the system while he was there, and actually he is

1 still there, the capacity of Hetchy increased on-  
2 peak from 360 MW to 405 MW now. That was really  
3 by tweaking, and he has often said that he would  
4 love to get his hands on some of the larger hydro  
5 projects and go in there and tweak for them.

6 If we use that as a benchmark, roughly  
7 ten percent potentially of the large conventional  
8 hydro units, you know, you could get 10 percent  
9 incremental capacity through repowering.

10 MR. TRASK: What is the nature of the  
11 tweaks?

12 MS. PARK: It has to do -- in the case  
13 of Hetchy, what he did was upgraded the generators  
14 and he changed out the turbine runners and did a  
15 bunch of other things with regard to the nozzles,  
16 you know, how they were directed so you got more  
17 efficiency out of the water. He is good at that.  
18 I don't think other people are looking hard enough  
19 at those options.

20 MR. TRASK: That was one things I was  
21 quite surprised with, both on supply and demand  
22 that generally you get a lot more out of an  
23 overhaul than you do -- let me get that right.  
24 You get a lot more out of an adjustment than you  
25 do out of an overhaul. That is whether it is an

1 adjustment in the pump or just your turbine

2 adjustment in the prime mover.

3 I was really surprised that you got that  
4 much improvement just out of simply a few hours of  
5 work.

6 MS. PARK: It was a little more than a  
7 few hours, but as far as the investment and the  
8 upgrade, if I recall properly, we paid -- it  
9 probably cost about 20 percent what the cost of a  
10 new unit with equivalent capacity would have  
11 taken, not to mention you can do it in a very  
12 short period of time.

13 MR. WOODWARD: You also didn't need to  
14 do all the permitting and all the other stuff for  
15 a repower.

16 One of the questions that you are asking  
17 us to look at is what about repowering of the  
18 existing hydro infrastructure and looking at the  
19 question of what qualifies for hydro under RPS.  
20 Okay, those are important questions for us to  
21 consider.

22 MR. TRASK: DOE did a big -- Energy  
23 Information Administration did a big study of  
24 hydro potential nationwide. As I recall, there  
25 was something like 5400 MWs at existing facilities

1 getting more generation. The head's already  
2 there, everything is all there, you just whatever  
3 modifications to the turbine or added turbines, I  
4 don't know what the mix there was, but pretty big  
5 number.

6 MR. WOODWARD: In the pumped storage  
7 question -- I am sort of walking our way down this  
8 list of things for us to go through if we can. In  
9 the pumped storage case, it seems that there are  
10 opportunities in your contractors systems if you  
11 will as much or more than there might be in yours  
12 for storage. I was taught down in San Diego, I  
13 think I mentioned earlier, but they have  
14 identified bunches of stuff where they could move  
15 water back uphill. They don't have a facility in  
16 place, they don't have the pump or the generator  
17 in place on their line. They have a pressure  
18 reducer, pressure control thing. So, they could  
19 replace and they can get electric to it, you know,  
20 if they could figure all of that out.

21 In San Diego's case, where pretty much  
22 everything is either up or down, it is a pretty  
23 good place to look. I have trouble seeing how you  
24 do that in Fresno, for example, it is a whole lot  
25 flatter, but you know, you take the opportunities

1 where they are.

2 What do you guys think about that, how  
3 would we find out more, and how would you  
4 recommend we sort of talk -- who should we talk  
5 to, to figure out stuff like that, any thoughts?

6 MR. ZASSO: Wouldn't you talk directly  
7 with San Diego? It sounds like --

8 MR. WOODWARD: In San Diego's case, but  
9 now I've got 50 other counties, 58 counties or  
10 something like that, I've got to talk to lots of  
11 folks.

12 MR. ZASSO: Our primary contract down in  
13 Southern California is the Metropolitan Water  
14 District, and they already looked in their own  
15 system for water supply liability improvements.  
16 They built the Diamond Valley Reservoir down in  
17 Southern California. That is around 800,000 acre  
18 feet when it is maximum.

19 They put a pump gen plant right there at  
20 the bottom. They pump it up. Water comes from  
21 our system. They pump it up into Diamond Valley,  
22 and they generate it out when they need it.

23 As far as what you are saying, they are  
24 already on the forefront of doing that. Their  
25 facility is on the Colorado River Aqueduct, they

1 are pumping from lower up to higher. There is not  
2 much I am thinking they can do with that. They do  
3 have some small reservoirs in there, but those  
4 facilities are built back in the 30's, so I don't  
5 know what opportunity there is for them to do  
6 that, any pump back type of operation there. I  
7 know there is no facilities there currently.

8 MR. WOODWARD: Given the energy that is  
9 attached to water in Southern California, it  
10 sounds like we ought to go talk to MWD and the  
11 folks at SERVES because MWD is a contractor of the  
12 State Water Project, but San Diego is not. They  
13 are a user of MWD water.

14 MR. ZASSO: Right, they are one of the  
15 member agencies.

16 MR. WOODWARD: Right, so it seems like  
17 we actually have to do that. Given the way the  
18 numbers are looking from out statewide study,  
19 right, Matt, where it is so much more expensive,  
20 that is what you just showed us as well. We ought  
21 to start looking at the southern part of the state  
22 at the end of your pipeline if you will because  
23 every gallon we don't have to -- if we could  
24 figure out ways to save gallons or store gallons  
25 down south, it has great value for the system.

1 UNIDENTIFIED VOICE: You just said talk

2 to SERVES, what would you talk to --

3 MR. BUI: No, the people that MWD

4 serves.

5 UNIDENTIFIED VOICE: Oh, that serves.

6 MR. WOODWARD: The people that MWD

7 serves, yes.

8 MS. NEWMARK: What about a few weeks, a

9 month and a half ago, we heard the gentleman, I

10 can't remember his name from Semitropic talking

11 about what the small instream generation that they

12 were creating in their system. That is an

13 entirely different scale than that which we are

14 talking about here, but again, if you do that

15 locally, the extent to which you can with very

16 small head --

17 MR. TRASK: I think that's one of the

18 big advances too that may change this whole water

19 system generation picture. Right now the

20 assessments are rather modest. I think the only

21 200 MWs or so in the conduit right now, but

22 there's been so much development lately in low

23 head high flow and the reverse hydro that maybe we

24 need to start from scratch.

25 MR. CROOKS: One of the things that I

1 ran into, I don't know if it is the right place  
2 for it, but looking at plants below 1 MW, low head  
3 hydro, the interconnection hurdles that exist with  
4 the serving utilities are completely subjective  
5 and almost insurmountable.

6 MR. TRASK: We hear that on the waste  
7 water generation as well. The digester --

8 MR. CROOKS: If these things don't  
9 loosen up, we can study these gizmos all we want,  
10 but until something changes about investor-owned  
11 utility access to the grid, it is not going to  
12 happen.

13 MR. TRASK: Well, we are the Energy  
14 Commission.

15 MR. WOODWARD: If that turns out to be  
16 one of the things we have to pay attention to is  
17 the interconnect issues related to any small scale  
18 distributed, in this case water.

19 MR. BROOME: I came across a case in  
20 point with the Semitropic Water Storage District  
21 where they were quite happy to think about 150 KW  
22 low head high flow installation on their canal,  
23 but only if they could use the power themselves.

24 The idea of selling it to a utility and  
25 then buying it back is no go. They have a

1 contract with PG & E that they buy it at one place  
2 only interconnection and that's it.

3 MR. WOODWARD: Right.

4 MR. BROOME: If they wanted to get a  
5 specific case, they would be happy to talk to you  
6 about that.

7 MR. WOODWARD: They have actually, but I  
8 guess one of the other things that sort of  
9 triggers is that Semitropic is a water banking  
10 district, so can water banking districts help the  
11 State Project?

12 MR. ZASSO: The flow is very small for  
13 us --

14 MR. WOODWARD: I understand from your  
15 point of view it is trivial, but --

16 MR. ZASSO: Where the Semitropic  
17 connection is, for example, is in the end of the  
18 Central Valley for us. It just goes right back  
19 into the canal. They either take it as a regular  
20 turn out or we have to actually physically lower  
21 the canal for them to pump back up into us. It is  
22 usually at rates anywhere from 50 to several 100  
23 CFS, very small, and we are pumping in that  
24 stretch, we would be pumping in the neighborhood  
25 of like say around 4,000 CFS, so it is just a very

1 small increment.

2 MR. WOODWARD: What if several water  
3 banking districts started to think about that,  
4 does it help? It really is a panacea, there  
5 really isn't any one thing to go after here.

6 MR. BUI: You have to be careful  
7 because extracting ground water has its own  
8 problem also. You can't extract -- if there is a  
9 certain way, if you extract too much, you are  
10 going to lower the water table, you are going to  
11 create another problem in the water supply issue  
12 also.

13 MR. ZASSO: The way a lot of the  
14 existing turn outs are configured, if you are  
15 going to do some type of arrangement like that, at  
16 times we are asked to lower the level in the  
17 aqueduct for these types of pump in applications,  
18 and at times, depending on the rate and the turn  
19 out, we have to flatten out our pumping in order  
20 to accommodate a lower a reservoir level. We  
21 can't pump full capacity, we have to pull it down  
22 slightly.

23 What that means for us is now we are  
24 instead of running 13 units at Edmunston on the  
25 off-peak period, I now can only run 11 or 12, now

1 I have to add extra pumping in the other hours to  
2 make that happen. It is not something we do very  
3 often. It is usually for some type of unusual  
4 event or in the case of a water transfer which are  
5 coordinated through our department from contractor  
6 to contractor, they have to pay the cost of doing  
7 that.

8 Again, there are operational issues that  
9 would have to no net impact to the department if  
10 there was an application like that.

11 MR. WOODWARD: It is a systemic impact,  
12 we can't just look at it as an individual case.

13 MR. ZASSO: Correct.

14 MR. BUI: It is also when you lower the  
15 canal basically to accept water, you pump at the  
16 lower, and you expend more energy to actually move  
17 the water also, so it might defeat the purposes.

18 MR. WOODWARD: Total energy balance  
19 might not look good at all is what I am trying to  
20 hear you say.

21 MS. NEWMARK: I haven't finished reading  
22 the whole draft, and maybe you addressed it here,  
23 but in an earlier discussion where we are really  
24 looking at the user's side. We talked a lot about  
25 the timing and the inertia in the water systems

1 and the fact that it is very different from the  
2 energy systems.

3 In a way, the State Water Project and  
4 the Valley Project are like your base  
5 load. We are talking about peakers every where  
6 else, and we are talking about the fact that the  
7 way the agriculture side runs is the farmer has to  
8 take 24 hours of flow from midnight to midnight or  
9 whenever the clock starts, but actually he only  
10 needs it during part of that day.

11 The problems with a system that is based  
12 on large bulk base loading where actually  
13 the demand is ideally intermittent if you tried to  
14 make it more effective for the purposes of use.

15 In a way, what I am hearing from you  
16 again is that we have a baseload, and if we want  
17 to accommodate, you know, Semitropic a 1 percent,  
18 5 percent thing, and yeah, we actually have to do  
19 something because 5 percent is not zero, but it  
20 has been an awkward thing.

21 Again, this speaks to our  
22 current infrastructure in the way we are trying to  
23 scotch tape and bandaids around it versus where we  
24 need to go in the next few decades.

25 Have you had any other experiences where

1 this shorter time frame accommodations can be made  
2 or what are the limitations. I think we have a  
3 general idea, and this kind of speaks to the ag  
4 discussion we had, which I haven't gotten to read  
5 about yet.

6 MR. TRASK: I did not write about this,  
7 I mean, yes, there are --

8 MS. NEWMARK: Forget it then.

9 MR. ZASSO: What (indiscernible) do you  
10 have about the ag, you mentioned that the  
11 contractors take a set amount over a 24 hour  
12 period. They may only need it for 12 or 16 hours  
13 for that particular day, but they let it run 24  
14 hours. That is primarily how a lot of our turn  
15 outs run. We do have some peak turn outs. A lot  
16 of them are 100 CFS for four days, and then they  
17 will go to a 150.

18 What it is, it is not so much a demand  
19 requirement, there is a demand need for that  
20 amount of water. In order to maximize -- they  
21 will take it that 24 hours because this farmer may  
22 have 30 miles that it has -- or the water district  
23 may have 30 miles they have to maintain or they  
24 have to operate to. A lot of the turn outs are  
25 not automated. They are set manually. There are

1 maybe one or two people that are managing that  
2 district that can't be at every turn out  
3 throughout the day to peak here, shut this one  
4 down, it is managed to where I need "X" amount of  
5 acre feet. Let's set this turn out to this flow,  
6 and we will patrol like we normally do. It is a  
7 physical issue a lot of times.

8 A lot of the districts are pretty wide  
9 spread. They don't have 30 or 40 people working  
10 for them, they may have a handful.

11 MR. TRASK: About in western Yolo County  
12 and the Yolo County Conservation District it's  
13 entire electric load consists of four gate  
14 controllers, gate valve controllers and no  
15 pumping. It is all gravity. Two canals it is  
16 automatic, a much simpler system.

17 MR. KLEIN: On the subject of pumped  
18 storage which was covered so well this morning,  
19 Tuan and Tio, thank you again for that. It  
20 impressed me a couple of things that maybe bears  
21 consideration for other potential products. One  
22 was the contractors who saw really a ten year  
23 financial investment for amortization recapture of  
24 that and for pumped storage just on an energy basis,  
25 that probably would involve some real risk taking

1 since the operation of that on a daily basis  
2 depends on that price differential and scheduling  
3 subject to all the constraints that may be unique  
4 and local.

5 That may be why in many cases people  
6 don't build pumped storage to take advantage of that  
7 peaking market.

8 MR. WOODWARD: You are partly saying we  
9 need to have a tariff that deals with that in some  
10 fashion.

11 MR. KLEIN: No, you just said that.

12 MR. WOODWARD: Okay.

13 MR. KLEIN: I was also impressed -- in  
14 your perspective in operating these pumped storage  
15 facilities, make use of them when you can that it  
16 has system benefits, but you don't operate it to  
17 benefit the system. You operate it to meet the  
18 beneficial needs of the State Water Project and  
19 the on-going mission at a least cost with  
20 acceptable risk. That way it helps build load in  
21 the off-peak hours, and it helps other generation  
22 operate more efficiently, but that is not your  
23 purpose.

24 MR. QUALLEY: In a sense, we are  
25 indirectly we are benefitting the entire system as

1 well because we are interconnected with the grid,  
2 and we are scheduled and coordinated with ISO. I  
3 mean the more we can smooth out our operations and  
4 have more operations because of the on-peak, that  
5 helps --

6 MR. KLEIN: Indeed. As a purchaser, it  
7 helps lower the energy costs as well. I guess one  
8 of the questions I would ask if knowing how the  
9 system is operating today for these investments  
10 made in pumped storage in the 60's, would you do it  
11 again for the limited types of frequency of use.

12 They have had a much longer life  
13 expectancy than ten years.

14 MR. QUALLEY: I want just make sure and  
15 clarify on the ten years. We just mentioned that  
16 number. It just so happened for this Tehachapi  
17 (indiscernible). There really isn't pumped storage.  
18 It is a peak flow I want to call it a reservoir --

19 MR. BUI: Off stream.

20 MR. QUALLEY: Off stream, peak flow  
21 facility to allow us to have a place to temporary  
22 store the water --

23 MR. WOODWARD: Sure more flexible  
24 pumping.

25 MR. QUALLEY: -- (indiscernible) off peak

1 pumping. As I recall the numbers in that  
2 particular project, it balanced based on the  
3 projections of off-peak and on-peak energy and the  
4 cost of that particular project. It happened to  
5 pay for itself in about ten years. I don't want  
6 you to get the idea that we use that as a criteria  
7 on all projects.

8        Obviously you want to build something  
9 that is going to pay for itself within a  
10 reasonable period of time.

11        MR. WOODWARD: One of the things that  
12 came up at one of our earlier workshops was  
13 presentation on sort of using the canal for  
14 generation, water flowing through the canal. Did  
15 any of you hear that presentation?

16        MR. QUALLEY: Didn't hear the  
17 presentation, but if you are talking about  
18 Verdent, then they have actually talked to us at  
19 the department.

20        MR. WOODWARD: What do you see in that?  
21 You are the engineers, tell us what you see.

22        MR. QUALLEY: Based on the particular  
23 type of equipment they were talking about, the  
24 flow in the aqueduct probably don't meet their  
25 criteria, it was probably less than half of what

1 they like to see. They were flowing about 10 feet  
2 per second as a minimum for efficient operation of  
3 the facilities they have were typically two to  
4 three feet per second in the aqueduct. It is a  
5 pretty slow moving system.

6 Plus there are maintenance issues with  
7 having additional equipment placed in the  
8 aqueduct. So, it is our overall conclusion from  
9 their presentation it probably wasn't a good  
10 application for the aqueduct.

11 MR. TRASK: Plus, I don't know the  
12 specifics on the aqueduct, but I know other  
13 agencies that have looked at that, their flows are  
14 so low that if you start putting a significant  
15 number of turbines down there, you actually can  
16 slow down even further --

17 MR. QUALLEY: That was another issue.

18 MR. TRASK: -- essentially adding head  
19 to your system. When you are two or three to  
20 begin with.

21 MR. WOODWARD: What about other instream  
22 flow generation capabilities. You describe one  
23 where your sort of instream is a pipe, one is  
24 instream of a stream, one is in stream of a canal.  
25 That is another one of our topics to think about.

1 Are there any opportunities you can see for in  
2 stream generation anywhere?

3 MR. QUALLEY: I know there have been a  
4 number of entities that have approached us, but  
5 with different types of concepts for that  
6 basically, some variation on some type of a vein  
7 or wheel arrangement. We haven't seen one yet  
8 that was applicable for the aqueduct.

9 MR. WOODWARD: What about things that  
10 are not aqueduct, anything that comes to mind?

11 MR. ZASSO: We discussed earlier about  
12 the Coastal Aqueduct. Again, the flow is at most  
13 maybe 110 CFS at a peak, and I do know when we  
14 built that pipeline that the environmental  
15 requirements in that area to get that pipeline put  
16 in drove the cost of the water essentially almost  
17 higher -- in fact it is higher than what is paid  
18 in Southern California, just by the cost of the  
19 environmental mitigation that the Department and  
20 the water contractors along that stretch have had  
21 to pay and will continue to pay. There is a  
22 theoretical number on the dollar per acre foot,  
23 and it is over \$700, per acre foot going into --

24 MR. TRASK: Was it (indiscernible)  
25 issues --

1 MR. ZASSO: What is that?

2 MR. TRASK: What were the issues?

3 MR. ZASSO: There were several  
4 endangered species that lived in the habitat in  
5 that area. There are lots of archeological  
6 sensitive areas within that pipeline stretch. So,  
7 you are balancing -- to put a recovery system in  
8 there, but the dollars to get there might be  
9 prohibitive.

10 MR. QUALLEY: What I will do, I will talk  
11 to the design staff in the project, the  
12 development staff that was involved in the Coastal  
13 Aqueduct, because I am sure that it had to have  
14 been considered in the process. I will get back  
15 to you with what the rational was.

16 MR. WOODWARD: That would be great.

17 MS. BURTON: It is my understanding that  
18 if someone has the contract with you for a certain  
19 amount of water, they have to use it or they lose  
20 it. I don't know if that is true or not, but that  
21 is my understanding is there is an incentive for  
22 people that have existing contracts to keep that  
23 water flowing to them. Is there any way that  
24 having more flexibility with your water  
25 requirement, what you have to supply for demand,

1 if that were more flexible, that you could improve  
2 your power generation and in some way give your  
3 customer an incentive to say, okay, I don't need  
4 my water, I am going to fallow my lands or  
5 whatever, so I want to convert that to energy and  
6 get that revenue in some way?

7 MR. QUALLEY: There are two types of  
8 costs of what the contractors pay. One is a fixed  
9 cost based on their full Table A, and that is what  
10 is used to allocate paying off the bond, the fixed  
11 type of cost. So, they are going to pay that  
12 whether they take a drop of water or not. The  
13 other costs are the variable transportation costs,  
14 and that is the cost of the energy, that is  
15 probably the primary component of the variable  
16 cost.

17 So, those are the two costs the  
18 contractor has, and my sense is the contractor  
19 signed up for the State Water Project because they  
20 needed the water, and they are going to request it  
21 because they needed the water. I don't think it  
22 is the idea that they feel that they have to take  
23 a certain amount of water.

24 MR. ZASSO: Our contracts with our water  
25 contractors, there is provision in them to be able

1 to store water from year to year without having to  
2 take it. It is called carry-over water, and it is  
3 typically most of the time it is stored in San  
4 Luis. There is some that is stored in Oroville.

5       What that allows them to do is if they  
6 have "X" amount of their Table A water for this  
7 year, they can earmark "X" amount of acre feet  
8 that they will store from this year to be used  
9 next year. There is a caveat that if any of those  
10 reservoirs fill, that water is spilt. It is no  
11 longer -- if we are filling it, they get their  
12 full request.

13       MR. BUI: Basically, it is not spill as  
14 in physical spill, it is theoretical spills  
15 meaning that it could have half a capacity at the  
16 pump and there is plenty of capacity or water to  
17 pump, and your water is sitting on top of the  
18 reservoir meaning the difference between what I  
19 can pump and what I can deliver to our contractor,  
20 that would be the spilling rate. There is no  
21 really physical spilling at all, it is just  
22 diverting water from the contractors,  
23 (indiscernible) contractor to the State Water  
24 Project.

25       MR. TRASK: Essentially, you have a que

1 and people get bumped out of the que.

2 MR. ZASSO: Right. Look at it in this  
3 range. It could be tagged as carry-over water  
4 here. If we start filling that reservoir, most  
5 likely it is going to be -- we are going to be  
6 able to provide that water than the normal Table A  
7 delivery for that year.

8 MR. BUI: Right.

9 MR. ZASSO: They are going to be made  
10 whole one way or the other.

11 MR. TRASK: This year might be one of  
12 those times where we would have to start bumping  
13 people since you are getting so much water  
14 (inaudible).

15 MR. BUI: You know, this year, we didn't  
16 spill that much of water so called spill. There  
17 is a carry-over water that is Article 21 water  
18 which is water they can take over above the  
19 entitlement. Meaning that you allocate a certain  
20 amount of water for a contractor. If water is  
21 plentiful, San Luis is full, and if you don't  
22 capture the water, the water is going to flow to  
23 the ocean. So, you capture the water and you say,  
24 hey, Contractor A, Contractor B, do you have any  
25 demand over and above your normal demand. Can you

1 accommodate this water. If they said yes, we  
2 would pump the water for them. Basically, is San  
3 Luis is filled, they take most of the water of  
4 carry-over out before it is all converted.

5 MR. TRASK: They would know it is  
6 coming.

7 MR. BUI: Yes, every year.

8 MR. ZASSO: Right.

9 MR. BROOME: I wonder if you know how  
10 the LA Department operates Castaic. I mean they  
11 have apparently a very satisfactory financial  
12 return the way they operate Castaic.

13 MR. ZASSO: It is all our water.

14 MR. BUI: Yes.

15 MR. BROOME: Pardon?

16 MR. ZASSO: It is all our water.

17 MR. BROOME: I know, your water, but  
18 their profit.

19 MR. ZASSO: Yes, we are well aware of  
20 that.

21 MR. BUI: Basically, we were originally  
22 putting in the recovery plans. They offered to  
23 put in the pump gen.

24 MR. QUALLEY: Could the person on the  
25 telephone, maybe muffle the microphone there.

1 MR. TRASK: That mike does not reach

2 him. That is James Park from LADWP --

3 MR. QUALLEY: Oh, this one doesn't reach

4 James.

5 UNIDENTIFIED VOICE: Give Ken my regards

6 if you will.

7 MR. TRASK: James are you there?

8 MR. PARK: Hello?

9 MR. TRASK: James, we are talking about  
10 you, I don't know if your ears got red there.

11 MR. PARK: Oh, I wasn't listening.

12 MR. TRASK: We just brought Castaic as a  
13 pumped storage resource. Can you tell us a little  
14 bit about your pumped storage operations?

15 MR. PARK: Oh gosh, I actually wouldn't  
16 be the person to talk about the operations. Is  
17 anyone from our power site on line by chance,  
18 Randy Howard?

19 MR. WOODWARD: I can jump in here just  
20 because I've -- let me jump over here.

21 MR. PARK: (Inaudible).

22 MR. WOODWARD: No, he is not here, but I  
23 did have the pleasure of talking to Randy and his  
24 staff over the last month. I am Jim Woodward with  
25 the Energy Commission, and DWP was real firm that

1 saying their net dependable capacity there at  
2 Castaic is 1175 MWs for one hour going forward.

3       They are adding about 10 MWs a year of  
4 capacity, but it is lower than nameplate because  
5 of the limitation hydraulically on the pen stock,  
6 but they integrate that with their system. They  
7 market the peaking energy when they can. It is my  
8 recollection that they needed a price differential  
9 between peak and off-peak energy of about 30  
10 percent since they were losing 15 percent of the  
11 value in each pass. A very efficient design  
12 system between (indiscernible) and Pyramid  
13 (indiscernible).

14       I recall them saying it is getting a  
15 little harder to find those markets, it is less  
16 frequent this year than it has been in past years  
17 for peaking energy. It is very important, and  
18 they look to using that for integrating 120 MWs  
19 nameplate of pine tree wind expected to come on  
20 early next year.

21       MR. ZASSO: One additional impact that  
22 we see as the level of our demand that we had on  
23 our West Branch that has increased over the last  
24 five or six years to where it would be normally  
25 down to the neighborhood of a couple of hundred

1 CFS in the winter time, now we are moving 500 to  
2 600 CFS at a minimum up to over a 1,000 CFS in the  
3 summertime.

4       There has been some impact. We are  
5 moving water in the pyramid on a daily and hourly  
6 basis, so they have to keep that into  
7 consideration when they are doing their pump back  
8 operation of operating pyramid within its normal  
9 operating range with additional water coming in.

10       Again, the level of demand on our West  
11 Branch and the level of water we've been  
12 delivering into the West Branch has increased  
13 considerably over the last four or five years.

14       MR. WOODWARD: What do you attribute it  
15 to? That's a big change.

16       MR. ZASSO: Part of it has to do with  
17 expansion down in Southern California. They are  
18 building houses and expanding all across Southern  
19 California, and some of it I would imagine is tied  
20 to the Colorado River Aqueduct. The cuts that MWD  
21 took on the Colorado, they are expanding their  
22 system eastward as much as they can and maximize  
23 their Colorado intact.

24       MR. BROOME: The gross head goes up at  
25 pyramid, and maybe the storage is less than the

1 eight to ten hours they had?

2 MR. ZASSO: Storage space, well, yeah,  
3 that is probably a good way to put that. Instead  
4 of us not having to pump during the day time or in  
5 the shoulder hours, they had more flexibility to  
6 move the pyramid up and down, we still have to  
7 keep that water moving in.

8 MR. KLEIN: They said that they give DWR  
9 credit for an average 45 MWs for the water that  
10 comes out the other end of the pipe, your through  
11 water.

12 MR. ZASSO: We were not here when those  
13 contracts were put into place, so, we won't take  
14 credit for those.

15 MR. BROOME: Has DWR ever considered the  
16 possibility of increasing the capacity of San Luis  
17 in particular to cope with the possibility of  
18 using excess capacity for daily operation?

19 MR. TRASK: Generating capacity I  
20 assume.

21 MR. BROOME: Generating and pumping. In  
22 other words, right now I understand that during  
23 the peak release season, you are using full  
24 capacity of release 24 hours a day, so you have no  
25 capacity for pumping.

1           MR. ZASSO: I won't say full capacity 24  
2 hours a day, but at peak delivery time during the  
3 year, we are going to fill up the majority of the  
4 day with delivery out of San Luis.

5           MR. KLEIN: If you had a south of Delta  
6 storage facility or --

7           MR. ZASSO: Los Banos ground --

8           MR. KLEIN: Yeah, Los Banos ground we'll  
9 put that one on the ground, it might actually  
10 enhance the pumped storage facilities that you have.

11          MR. ZASSO: Potentially. I don't know.  
12 Those are years, if not decades away.

13          MR. KLEIN: I don't think they are on  
14 the table compared to --

15          MR. ZASSO: Right.

16          MR. WOODWARD: We have a few other topic  
17 areas here of questions, conduit hydro, digester,  
18 gas generation, and other renewable generation.  
19 Anybody have any thoughts on that?

20          MS. PARK: I just want to mention, I  
21 think that you are probably aware that we are  
22 (inaudible) -- am I doing it again -- on the  
23 statewide potential for in conduit hydro, that  
24 scope is still deliberately limited because of the  
25 intent of finding RPS eligible hydro.

1       Again, we go back to a need to assess  
2   what the state's goals are in context of its  
3   policy for our RPS because, for example, we did  
4   not consider in stream hydro in this study, it is  
5   only manmade conduits which are ditches, canals,  
6   pipelines. The other thing that we didn't include  
7   in this scope, but has merit to look at -- and we  
8   didn't include it in the scope for a couple of  
9   reasons, but the primary reason was that we are  
10   having a lot of difficulty getting this kind of  
11   information from the water utilities in view of  
12   infrastructure security concerns, and that is the  
13   location of pressure reducing valves, which I  
14   understand are not only good potential for hydro,  
15   but also really good potential for infiltration  
16   into the water supply.

17       We could only do to the extent we bumped  
18   across those, we identified them. I just wanted  
19   to let you know that is in process.

20       MR. WOODWARD: Roughly when?

21       MS. PARK: We are actually about ready  
22   to wrap that study up, and so I think the final  
23   draft report would be ready in about a month, but  
24   you might want to confer with Mike King on that.

25       MR. TRASK: The figures that I have in

1 my report came from Mike, so essentially the same  
2 information. Mike in ACWA.

3 MS. PARK: Right. One other thought on  
4 the digester gas, I understand also  
5 (indiscernible), I don't know much about it is  
6 doing studies on the dairy manure issue. I never  
7 would have thought of digester gas and Gary or  
8 anyone thought, until I met Martha Davis, who  
9 wants to put it all together and make this really  
10 fabulous feed stock and generate the heck out of  
11 it. I just wanted to mention that.

12 MR. TRASK: Composting facilities.

13 MS. PARK: Yes, very fascinating. I  
14 never thought of it before.

15 MS. NEWMARK: Actually, we had a meeting  
16 with Western United Dairymen, and we were actually  
17 talking about air emissions. We weren't talking  
18 about power generation. Their issues with respect  
19 to the digester also revolved around what kind of  
20 greenhouse gasses were emitting and overall what  
21 the impact to global warming and air quality, vis  
22 a vis the reactive gasses versus the ones that are  
23 actually regulated. That is a big issue in the  
24 Central Valley.

25 Since the air quality issues seem to be

1 wagging the dog with respect to the use of these  
2 four dairies in particular, but also smaller  
3 generators of fuel. In a way, I don't know what  
4 the Commission could do to address this, but I  
5 think that there is a combined issue with respect  
6 to energy generation, air quality, and long term  
7 impact to our environment that you are going to  
8 have to get up above the individual trees and  
9 start looking at the forest. So, I am just kind  
10 of throwing that back in your lap, but I think  
11 something positive could be done through your  
12 offices.

13 MR. TRASK: The conclusion was that  
14 digester gas generation can actually lower  
15 greenhouse gas because of emissions?

16 MS. PARK: Right now it is being  
17 regulated and what they are talking about  
18 permitting is basically -- well, the comment that  
19 was given was that there was no science involved  
20 in the decision. There was sort of a list of  
21 chemicals and numbers thrown at them that were not  
22 very well generated. Unfortunately, those  
23 permitted materials did not include things that  
24 were very reactive and were ozone precursors and  
25 that were the difference between methane and CO2

1 and some of the others. Some of them you would  
2 actually end up with an increase emission rate of  
3 things that were worse long term for the  
4 environment, but they just weren't off the  
5 specific list.

6       It was sort of a well intentioned, but  
7 not well thought out implementation. As a result,  
8 there was a barrier to some of the larger sources  
9 to go forward with this because they felt they  
10 were being -- how do I say it, in appropriately  
11 managed, and it wasn't going to serve the purpose,  
12 so why do it after all. You know, look for  
13 another option. Given that energy production is  
14 very important to us here and the long term  
15 impacts to the environment, this discussion has  
16 sort of a longer term view, perhaps visiting those  
17 emission issues in that context might be helpful  
18 because otherwise they are being regulated on a  
19 very local basis without a statewide view.

20       MR. TRASK: I think that is crucial.  
21 The few people that have been looking at digester  
22 gas but decided not to go through with it, one of  
23 the big issues was buying the air emission offset  
24 credits. I mean, that is a huge expense right  
25 now. If there is any benefit that they are

1 supplying, I don't think that is factored into the  
2 equation at all.

3 MS. PARK: I wanted to mention something  
4 that Martha Davis had mentioned to me, and I am  
5 sure I am going to get it wrong, so I will then  
6 after I leave this meeting ask her for the correct  
7 quote. That is, she told me that she had been in  
8 negotiations, and I thought it was with the local  
9 air district about getting appropriate credit for  
10 bringing the dairy manure into the feed stock for  
11 this waste water treatment.

12 The issue was that by moving the dairy  
13 manure, she was solving one air pollution, and yes  
14 she was converting it to a different problem, but  
15 she wanted full credit for the total package. She  
16 said that she had gotten some agreement that is  
17 how they would treat it, but like I said I would  
18 get more information from her.

19 MR. TRASK: That is what I was getting  
20 at, right now you don't get any credit for  
21 reducing greenhouse gas emissions, only the  
22 criteria pollutants, some of which are, but they  
23 are not really a correlation between the two.

24 MS. BURTON: There should be some  
25 potential credit as well for the ground water

1 pollution that is avoided by not spreading the  
2 manure.

3 MR. WOODWARD: Unfortunately, it is a  
4 different agency that regulates that one, and so  
5 it is hard to get all the permittees to agree  
6 that, yes, you have done something positive or  
7 negative. I think you are right that we ought to  
8 have some discussions with folks that understand  
9 the complexity and look through possible  
10 solutions. It makes sense to do that.

11 MR. TRASK: Gary, I kind feel like we  
12 should probably wrap this up if we are going to  
13 have any time to do comments today. Do people  
14 want to go into comments on the study today, or  
15 should we just save that for Thursday? Silence  
16 is --

17 MR. WOODWARD: I am going to propose a  
18 slight change in that discussion. This is  
19 primarily for the folks here from DWR, we are  
20 looking for ideas that the State, not just the  
21 Energy Commission, but that the State ought to  
22 undertake in the context of this Integrated Energy  
23 Policy Report to do things that would be better  
24 than where we are out now. Things we ought to  
25 look at, suggestions for us to pay attention to,

1 all that stuff. If you have any of those  
2 now, we would love to hear them. If not, and you  
3 want to think about them, we would love to hear  
4 them when you are ready to tell us.

5 We are very interested in your thoughts  
6 as to how we might do things better or  
7 differently. You can point to us or you can point  
8 to others or yourselves, whatever it is, we are  
9 interested.

10 MR. QUALLEY: I don't have any particular  
11 things I came today to offer. I think the  
12 Department's continued involvement I think will be  
13 probably primarily through the Bulletin 160 side  
14 of the house that has the overall  
15 statewide picture on the water planning.  
16 Certainly those of us on the State Water Project  
17 side will be working with them and supporting  
18 that. I'm not sure if Paul will have some of  
19 those additional ideas from that perspective.

20 MR. TRASK: I did talk with Paul last  
21 Friday, and he said that many people in the  
22 Statewide Planning Office are reviewing the paper  
23 and will be getting those comments.

24 MR. QUALLEY: Paul and I are in  
25 communication as far as coordinating comments.

1 MR. WOODWARD: If you can think of  
2 anything, we are interested in hearing about it.

3 MR. BROOME: I'd like to make one more  
4 suggestion, and that is, at one time, some private  
5 developer was planning an underground pumped storage  
6 project somewhere in the Mojave Desert area.  
7 Underground pumped storage has been tried both in  
8 the Midwestern also in New England, or Mid  
9 Atlantic area mainly because it isolates the  
10 project from any environmental impact.

11 In other words, you've got a self-  
12 contained system, you've run the water down, and  
13 no fish, no major impact of the surface. So, if  
14 you are looking for something like 10,000 MWs of  
15 pumped storage capacity. I think an underground  
16 facility in the Mojave Desert might be a good  
17 idea.

18 MR. TRASK: The paper talks about  
19 modular pumped storage and it can be virtually any  
20 kind of container, underground, or above ground  
21 tank, open reservoir, or whatever, but you only  
22 charge it once, and then whatever make up you have  
23 after that, so it is not a consumptive use. I  
24 think there is a lot of potential in that.

25 MR. BROOME: Cost wise, it may sound

1 like a lot of money to dig a hole in the ground,  
2 but in fact, it doesn't come to that much more  
3 than surface reservoirs. If you have a vertical  
4 pen stock, that's the shortest distance between  
5 the upper and lower reservoir, and that is the  
6 ideal from a pumped storage plant designers point of  
7 view. That is something from state point of view,  
8 it may be something to encourage somebody in the  
9 private sector to undertake.

10 MR. WOODWARD: Okay. I think unless you  
11 really want us to spend time on comments, I have a  
12 feeling that a lot of folks here look tired, and  
13 we ought to ask them to come back fresh on  
14 Thursday.

15 MR. TRASK: I have a feeling that I am  
16 very tired, so that sounds very good to me.

17 MR. WOODWARD: Let's call it a day then.

18 MR. TRASK: Okay.

19 (Whereupon, at 2:43 p.m., the workshop  
20 was adjourned.)

CERTIFICATE OF REPORTER

I, CHRISTOPHER LOVERRO, an Electronic Reporter, do hereby certify that I am a disinterested person herein; that I recorded the foregoing California Energy Commission Working Group; that it was thereafter transcribed into typewriting.

I further certify that I am not of counsel or attorney for any of the parties to said working group, nor in any way interested in outcome of said working group.

IN WITNESS WHEREOF, I have hereunto set my hand this 7th day of June, 2005.
